Package 'loo'

July 3, 2024

```
Title Efficient Leave-One-Out Cross-Validation and WAIC for Bayesian
     Models
Version 2.8.0
Date 2024-07-03
Maintainer Jonah Gabry < jsg2201@columbia.edu>
URL https://mc-stan.org/loo/, https://discourse.mc-stan.org
BugReports https://github.com/stan-dev/loo/issues
Description Efficient approximate leave-one-out cross-validation (LOO)
     for Bayesian models fit using Markov chain Monte Carlo, as
     described in Vehtari, Gelman, and Gabry (2017)
     <doi:10.1007/s11222-016-9696-4>.
     The approximation uses Pareto smoothed importance sampling (PSIS),
     a new procedure for regularizing importance weights.
     As a byproduct of the calculations, we also obtain approximate
     standard errors for estimated predictive errors and for the comparison
     of predictive errors between models. The package also provides methods
     for using stacking and other model weighting techniques to average
     Bayesian predictive distributions.

loo-package

Efficient LOO-CV and WAIC for Bayesian models

Description

Stan Development Team

This package implements the methods described in Vehtari, Gelman, and Gabry (2017), Vehtari, Simpson, Gelman, Yao, and Gabry (2024), and Yao et al. (2018). To get started see the **loo** package vignettes, the loo() function for efficient approximate leave-one-out cross-validation (LOO-CV), the psis() function for the Pareto smoothed importance sampling (PSIS) algorithm, or loo_model_weights() for an implementation of Bayesian stacking of predictive distributions from multiple models.

Details

Leave-one-out cross-validation (LOO-CV) and the widely applicable information criterion (WAIC) are methods for estimating pointwise out-of-sample prediction accuracy from a fitted Bayesian model using the log-likelihood evaluated at the posterior simulations of the parameter values. LOO-CV and WAIC have various advantages over simpler estimates of predictive error such as AIC and DIC but are less used in practice because they involve additional computational steps. This package implements the fast and stable computations for approximate LOO-CV laid out in Vehtari, Gelman, and Gabry (2017). From existing posterior simulation draws, we compute LOO-CV using Pareto smoothed importance sampling (PSIS; Vehtari, Simpson, Gelman, Yao, and Gabry, 2024), a new procedure for stabilizing and diagnosing importance weights. As a byproduct of our calculations, we also obtain approximate standard errors for estimated predictive errors and for comparing of predictive errors between two models.

We recommend PSIS-LOO-CV instead of WAIC, because PSIS provides useful diagnostics and effective sample size and Monte Carlo standard error estimates.

ap_psis Pareto smoothed importance sampling (PSIS) using approximate posteriors

Description

Pareto smoothed importance sampling (PSIS) using approximate posteriors

Usage

```
ap_psis(log_ratios, log_p, log_g, ...)
## S3 method for class 'array'
ap_psis(log_ratios, log_p, log_g, ..., cores = getOption("mc.cores", 1))
## S3 method for class 'matrix'
ap_psis(log_ratios, log_p, log_g, ..., cores = getOption("mc.cores", 1))
## Default S3 method:
ap_psis(log_ratios, log_p, log_g, ...)
```

Arguments

log_ratios	The log-likelihood ratios (ie -log_liks)
log_p	The log-posterior (target) evaluated at S samples from the proposal distribution (g). A vector of length S .
log_g	The log-density (proposal) evaluated at S samples from the proposal distribution (g). A vector of length S.
	Currently not in use.

6 compare

cores

The number of cores to use for parallelization. This defaults to the option mc.cores which can be set for an entire R session by options(mc.cores = NUMBER). The old option loo.cores is now deprecated but will be given precedence over mc.cores until loo.cores is removed in a future release. As of version 2.0.0 the default is now 1 core if mc.cores is not set, but we recommend using as many (or close to as many) cores as possible.

• Note for Windows 10 users: it is **strongly** recommended to avoid using the .Rprofile file to set mc.cores (using the cores argument or setting mc.cores interactively or in a script is fine).

Methods (by class)

- ap_psis(array): An I by C by N array, where I is the number of MCMC iterations per chain, C is the number of chains, and N is the number of data points.
- ap_psis(matrix): An S by N matrix, where S is the size of the posterior sample (with all chains merged) and N is the number of data points.
- ap_psis(default): A vector of length S (posterior sample size).

compare

Model comparison (deprecated, old version)

Description

This function is deprecated. Please use the new loo_compare() function instead.

Usage

```
compare(..., x = list())
```

Arguments

... At least two objects returned by loo() (or waic()).

A list of at least two objects returned by loo() (or waic()). This argument can be used as an alternative to specifying the objects in

Details

When comparing two fitted models, we can estimate the difference in their expected predictive accuracy by the difference in elpd_loo or elpd_waic (or multiplied by -2, if desired, to be on the deviance scale).

When that difference, elpd_diff, is positive then the expected predictive accuracy for the second model is higher. A negative elpd_diff favors the first model.

When using compare() with more than two models, the values in the elpd_diff and se_diff columns of the returned matrix are computed by making pairwise comparisons between each model and the model with the best ELPD (i.e., the model in the first row). Although the elpd_diff

crps 7

column is equal to the difference in elpd_loo, do not expect the se_diff column to be equal to the the difference in se_elpd_loo.

To compute the standard error of the difference in ELPD we use a paired estimate to take advantage of the fact that the same set of N data points was used to fit both models. These calculations should be most useful when N is large, because then non-normality of the distribution is not such an issue when estimating the uncertainty in these sums. These standard errors, for all their flaws, should give a better sense of uncertainty than what is obtained using the current standard approach of comparing differences of deviances to a Chi-squared distribution, a practice derived for Gaussian linear models or asymptotically, and which only applies to nested models in any case.

Value

A vector or matrix with class 'compare.loo' that has its own print method. If exactly two objects are provided in ... or x, then the difference in expected predictive accuracy and the standard error of the difference are returned. If more than two objects are provided then a matrix of summary information is returned (see **Details**).

Examples

```
## Not run:
loo1 <- loo(log_lik1)
loo2 <- loo(log_lik2)
print(compare(loo1, loo2), digits = 3)
print(compare(x = list(loo1, loo2)))

waic1 <- waic(log_lik1)
waic2 <- waic(log_lik2)
compare(waic1, waic2)

## End(Not run)</pre>
```

8 crps

Description

The crps() and scrps() functions and their loo_*() counterparts can be used to compute the continuously ranked probability score (CRPS) and scaled CRPS (SCRPS) (see Bolin and Wallin, 2022). CRPS is a proper scoring rule, and strictly proper when the first moment of the predictive distribution is finite. Both can be expressed in terms of samples form the predictive distribution. See e.g. Gneiting and Raftery (2007) for a comprehensive discussion on CRPS.

Usage

```
crps(x, ...)
scrps(x, ...)
loo_{crps}(x, ...)
loo_scrps(x, ...)
## S3 method for class 'matrix'
crps(x, x2, y, ..., permutations = 1)
## S3 method for class 'numeric'
crps(x, x2, y, ..., permutations = 1)
## S3 method for class 'matrix'
loo_crps(
  Χ,
  x2,
  у,
  log_lik,
  permutations = 1,
  r_eff = 1,
  cores = getOption("mc.cores", 1)
)
## S3 method for class 'matrix'
scrps(x, x2, y, ..., permutations = 1)
## S3 method for class 'numeric'
scrps(x, x2, y, ..., permutations = 1)
## S3 method for class 'matrix'
loo_scrps(
  Х,
  x2,
  log_lik,
  . . . ,
```

crps 9

```
permutations = 1,
  r_eff = 1,
  cores = getOption("mc.cores", 1)
)
```

Arguments

X	A S by N matrix (draws by observations), or a vector of length S when only single observation is provided in y.
	Passed on to E_loo() in the loo_*() version of these functions.
x2	Independent draws from the same distribution as draws in \boldsymbol{x} . Should be of the identical dimension.
у	A vector of observations or a single value.
permutations	An integer, with default value of 1, specifying how many times the expected value of $ X - X' $ ($ x - x2 $) is computed. The row order of x2 is shuffled as elements x and x2 are typically drawn given the same values of parameters. This happens, e.g., when one calls posterior_predict() twice for a fitted rstanarm or brms model. Generating more permutations is expected to decrease the variance of the computed expected value.
log_lik	A log-likelihood matrix the same size as x.
r_eff	An optional vector of relative effective sample size estimates containing one element per observation. See psis() for details.
cores	The number of cores to use for parallelization of [psis()]. See psis() for details.

Details

To compute (S)CRPS, the user needs to provide two sets of draws, x and x2, from the predictive distribution. This is due to the fact that formulas used to compute CRPS involve an expectation of the absolute difference of x and x2, both having the same distribution. See the permutations argument, as well as Gneiting and Raftery (2007) for details.

Value

A list containing two elements: estimates and pointwise. The former reports estimator and standard error and latter the pointwise values.

10 elpd

Examples

```
## Not run:
# An example using rstanarm
library(rstanarm)
data("kidiq")
fit <- stan_glm(kid_score ~ mom_hs + mom_iq, data = kidiq)
ypred1 <- posterior_predict(fit)
ypred2 <- posterior_predict(fit)
crps(ypred1, ypred2, y = fit$y)
loo_crps(ypred1, ypred2, y = fit$y, log_lik = log_lik(fit))
## End(Not run)</pre>
```

elpd

Generic (expected) log-predictive density

Description

The elpd() methods for arrays and matrices can compute the expected log pointwise predictive density for a new dataset or the log pointwise predictive density of the observed data (an overestimate of the elpd).

Usage

```
elpd(x, ...)
## S3 method for class 'array'
elpd(x, ...)
## S3 method for class 'matrix'
elpd(x, ...)
```

Arguments

x A log-likelihood array or matrix. The **Methods** (**by class**) section, below, has detailed descriptions of how to specify the inputs for each method.

... Currently ignored.

Details

The elpd() function is an S3 generic and methods are provided for 3-D pointwise log-likelihood arrays and matrices.

example_loglik_array 11

Methods (by class)

- elpd(array): An I by C by N array, where I is the number of MCMC iterations per chain,
 C is the number of chains, and N is the number of data points.
- elpd(matrix): An S by N matrix, where S is the size of the posterior sample (with all chains merged) and N is the number of data points.

See Also

The vignette *Holdout validation and K-fold cross-validation of Stan programs with the loo package* for demonstrations of using the elpd() methods.

Examples

```
# Calculate the lpd of the observed data
LLarr <- example_loglik_array()
elpd(LLarr)</pre>
```

```
example_loglik_array Objects to use in examples and tests
```

Description

Example pointwise log-likelihood objects to use in demonstrations and tests. See the **Value** and **Examples** sections below.

Usage

```
example_loglik_array()
example_loglik_matrix()
```

Value

example_loglik_array() returns a $500 \text{ (draws)} \times 2 \text{ (chains)} \times 32 \text{ (observations)}$ pointwise log-likelihood array.

example_loglik_matrix() returns the same pointwise log-likelihood values as example_loglik_array() but reshaped into a $1000 \text{ (draws*chains)} \times 32 \text{ (observations)}$ matrix.

Examples

```
LLarr <- example_loglik_array()
(dim_arr <- dim(LLarr))
LLmat <- example_loglik_matrix()
(dim_mat <- dim(LLmat))

all.equal(dim_mat[1], dim_arr[1] * dim_arr[2])
all.equal(dim_mat[2], dim_arr[3])</pre>
```

12 extract_log_lik

```
all.equal(LLarr[, 1, ], LLmat[1:500, ])
all.equal(LLarr[, 2, ], LLmat[501:1000, ])
```

extract_log_lik

Extract pointwise log-likelihood from a Stan model

Description

Convenience function for extracting the pointwise log-likelihood matrix or array from a stanfit object from the **rstan** package. Note: recent versions of **rstan** now include a loo() method for stanfit objects that handles this internally.

Usage

```
extract_log_lik(stanfit, parameter_name = "log_lik", merge_chains = TRUE)
```

Arguments

stanfit A stanfit object (**rstan** package).

parameter_name A character string naming the parameter (or generated quantity) in the Stan

model corresponding to the log-likelihood.

merge_chains If TRUE (the default), all Markov chains are merged together (i.e., stacked) and a

matrix is returned. If FALSE they are kept separate and an array is returned.

Details

Stan does not automatically compute and store the log-likelihood. It is up to the user to incorporate it into the Stan program if it is to be extracted after fitting the model. In a Stan model, the pointwise log likelihood can be coded as a vector in the transformed parameters block (and then summed up in the model block) or it can be coded entirely in the generated quantities block. We recommend using the generated quantities block so that the computations are carried out only once per iteration rather than once per HMC leapfrog step.

For example, the following is the generated quantities block for computing and saving the log-likelihood for a linear regression model with N data points, outcome y, predictor matrix X, coefficients beta, and standard deviation sigma:

```
vector[N] log_lik;
for (n in 1.N) log_lik[n] = normal_lndf(v[n] | )
```

```
for (n in 1:N) log_lik[n] = normal_lpdf(y[n] | X[n, ] * beta, sigma);
```

Value

If merge_chains=TRUE, an S by N matrix of (post-warmup) extracted draws, where S is the size of the posterior sample and N is the number of data points. If merge_chains=FALSE, an I by C by N array, where $I \times C = S$.

E_loo 13

E_loo

Compute weighted expectations

Description

The E_loo() function computes weighted expectations (means, variances, quantiles) using the importance weights obtained from the PSIS smoothing procedure. The expectations estimated by the E_loo() function assume that the PSIS approximation is working well. A small Pareto k estimate is necessary, but not sufficient, for E_loo() to give reliable estimates. Additional diagnostic checks for gauging the reliability of the estimates are in development and will be added in a future release.

Usage

```
E_loo(x, psis_object, ...)
## Default S3 method:
E_loo(
  х,
  psis_object,
  type = c("mean", "variance", "sd", "quantile"),
  probs = NULL,
  log_ratios = NULL
## S3 method for class 'matrix'
E_loo(
  х,
  psis_object,
  type = c("mean", "variance", "sd", "quantile"),
  probs = NULL,
  log_ratios = NULL
)
```

Arguments

```
x A numeric vector or matrix.psis_object An object returned by psis().... Arguments passed to individual methods.
```

14 E_loo

type The type of expectation to compute. The options are "mean", "variance",

"sd", and "quantile".

probs For computing quantiles, a vector of probabilities.

log_ratios Optionally, a vector or matrix (the same dimensions as x) of raw (not smoothed)

log ratios. If working with log-likelihood values, the log ratios are the **negative** of those values. If log_ratios is specified we are able to compute more

accurate Pareto k diagnostics specific to E_loo().

Value

A named list with the following components:

value The result of the computation.

For the matrix method, value is a vector with ncol(x) elements, with one exception: when type="quantile" and multiple values are specified in probs the value component of the returned object is a length(probs) by ncol(x) matrix.

For the default/vector method the value component is scalar, with one exception: when type="quantile" and multiple values are specified in probs the value component is a vector with length(probs) elements.

pareto_k Function-specific diagnostic.

For the matrix method it will be a vector of length ncol(x) containing estimates of the shape parameter k of the generalized Pareto distribution. For the default/vector method, the estimate is a scalar. If log_ratios is not specified when calling log_ratios , the smoothed log_ratios are used to estimate Pareto-k's, which may produce optimistic estimates.

For type="mean", type="var", and type="sd", the returned Pareto-k is usually the maximum of the Pareto-k's for the left and right tail of hr and the right tail of r, where r is the importance ratio and h=x for type="mean" and $h=x^2$ for type="var" and type="sd". If h is binary, constant, or not finite, or if type="quantile", the returned Pareto-k is the Pareto-k for the right tail of r.

Examples

```
if (requireNamespace("rstanarm", quietly = TRUE)) {
# Use rstanarm package to quickly fit a model and get both a log-likelihood
# matrix and draws from the posterior predictive distribution
library("rstanarm")

# data from help("lm")
ctl <- c(4.17,5.58,5.18,6.11,4.50,4.61,5.17,4.53,5.33,5.14)
trt <- c(4.81,4.17,4.41,3.59,5.87,3.83,6.03,4.89,4.32,4.69)
d <- data.frame(
    weight = c(ctl, trt),
    group = gl(2, 10, 20, labels = c("Ctl","Trt"))
)
fit <- stan_glm(weight ~ group, data = d, refresh = 0)
yrep <- posterior_predict(fit)
dim(yrep)

log_ratios <- -1 * log_lik(fit)</pre>
```

gpdfit 15

```
dim(log_ratios)

r_eff <- relative_eff(exp(-log_ratios), chain_id = rep(1:4, each = 1000))
psis_object <- psis(log_ratios, r_eff = r_eff, cores = 2)

E_loo(yrep, psis_object, type = "mean")
E_loo(yrep, psis_object, type = "var")
E_loo(yrep, psis_object, type = "sd")
E_loo(yrep, psis_object, type = "quantile", probs = 0.5) # median
E_loo(yrep, psis_object, type = "quantile", probs = c(0.1, 0.9))

# We can get more accurate Pareto k diagnostic if we also provide
# the log_ratios argument
E_loo(yrep, psis_object, type = "mean", log_ratios = log_ratios)
}</pre>
```

gpdfit

Estimate parameters of the Generalized Pareto distribution

Description

Given a sample x, Estimate the parameters k and σ of the generalized Pareto distribution (GPD), assuming the location parameter is 0. By default the fit uses a prior for k, which will stabilize estimates for very small sample sizes (and low effective sample sizes in the case of MCMC samples). The weakly informative prior is a Gaussian prior centered at 0.5.

Usage

```
gpdfit(x, wip = TRUE, min_grid_pts = 30, sort_x = TRUE)
```

Arguments

X	A numeric vector. The sample from which to estimate the parameters.
wip	Logical indicating whether to adjust k based on a weakly informative Gaussian prior centered on 0.5. Defaults to TRUE.
min_grid_pts	The minimum number of grid points used in the fitting algorithm. The actual number used is $min_grid_pts + floor(sqrt(length(x)))$.
sort_x	If TRUE (the default), the first step in the fitting algorithm is to sort the elements of x. If x is already sorted in ascending order then sort_x can be set to FALSE to skip the initial sorting step.

Details

Here the parameter k is the negative of k in Zhang & Stephens (2009).

Value

A named list with components k and sigma.

References

Zhang, J., and Stephens, M. A. (2009). A new and efficient estimation method for the generalized Pareto distribution. *Technometrics* **51**, 316-325.

See Also

```
psis(), pareto-k-diagnostic
```

importance_sampling

A parent class for different importance sampling methods.

Description

A parent class for different importance sampling methods.

Usage

```
importance_sampling(log_ratios, method, ...)
## S3 method for class 'array'
importance_sampling(
 log_ratios,
 method,
 r_eff = 1,
 cores = getOption("mc.cores", 1)
)
## S3 method for class 'matrix'
importance_sampling(
 log_ratios,
 method,
 r_eff = 1,
 cores = getOption("mc.cores", 1)
## Default S3 method:
importance_sampling(log_ratios, method, ..., r_eff = 1)
```

kfold-generic 17

Arguments

log_ratios

An array, matrix, or vector of importance ratios on the log scale (for PSIS-LOO these are *negative* log-likelihood values). See the **Methods** (**by class**) section below for a detailed description of how to specify the inputs for each method.

method

The importance sampling method to use. The following methods are implemented:

- "psis": Pareto-Smoothed Importance Sampling (PSIS). Default method.
- "tis": Truncated Importance Sampling (TIS) with truncation at sqrt(S), where S is the number of posterior draws.
- "sis": Standard Importance Sampling (SIS).

. . . Arguments passed on to the various methods.

r_eff

Vector of relative effective sample size estimates containing one element per observation. The values provided should be the relative effective sample sizes of $1/\exp(\log_ratios)$ (i.e., 1/ratios). This is related to the relative efficiency of estimating the normalizing term in self-normalizing importance sampling. If r_eff is not provided then the reported PSIS effective sample sizes and Monte Carlo error estimates can be over-optimistic. If the posterior draws are (near) independent then $r_eff=1$ can be used. r_eff has to be a scalar (same value is used for all observations) or a vector with length equal to the number of observations. The default value is 1. See the $relative_eff()$ helper function for computing r_eff .

cores

The number of cores to use for parallelization. This defaults to the option mc.cores which can be set for an entire R session by options(mc.cores = NUMBER). The old option loo.cores is now deprecated but will be given precedence over mc.cores until loo.cores is removed in a future release. As of version 2.0.0 the default is now 1 core if mc.cores is not set, but we recommend using as many (or close to as many) cores as possible.

• Note for Windows 10 users: it is **strongly** recommended to avoid using the .Rprofile file to set mc.cores (using the cores argument or setting mc.cores interactively or in a script is fine).

kfold-generic

Generic function for K-fold cross-validation for developers

Description

For developers of Bayesian modeling packages, **loo** includes a generic function kfold() so that methods may be defined for K-fold CV without name conflicts between packages. See, for example, the kfold() methods in the **rstanarm** and **brms** packages.

The **Value** section below describes the objects that kfold() methods should return in order to be compatible with loo_compare() and the **loo** package print methods.

18 kfold-helpers

Usage

```
kfold(x, ...)
is.kfold(x)
```

Arguments

x A fitted model object.

... Arguments to pass to specific methods.

Value

For developers defining a kfold() method for a class "foo", the kfold.foo() function should return a list with class c("kfold", "loo") with at least the following named elements:

- "estimates": A 1x2 matrix containing the ELPD estimate and its standard error. The matrix must have row name "elpd_kfold" and column names "Estimate" and "SE".
- "pointwise": A Nx1 matrix with column name "elpd_kfold" containing the pointwise contributions for each data point.

It is important for the object to have at least these classes and components so that it is compatible with other functions like loo_compare() and print() methods.

kfold-helpers

Helper functions for K-fold cross-validation

Description

These functions can be used to generate indexes for use with K-fold cross-validation. See the **Details** section for explanations.

Usage

```
kfold_split_random(K = 10, N = NULL)
kfold_split_stratified(K = 10, x = NULL)
kfold_split_grouped(K = 10, x = NULL)
```

Arguments

K The number of folds to use.

N The number of observations in the data.

x A discrete variable of length N with at least K levels (unique values). Will be coerced to a factor.

loo 19

Details

kfold_split_random() splits the data into K groups of equal size (or roughly equal size).

For a categorical variable x kfold_split_stratified() splits the observations into K groups ensuring that relative category frequencies are approximately preserved.

For a grouping variable x, kfold_split_grouped() places all observations in x from the same group/level together in the same fold. The selection of which groups/levels go into which fold (relevant when when there are more groups than folds) is randomized.

Value

An integer vector of length N where each element is an index in 1:K.

Examples

```
ids <- kfold_split_random(K = 5, N = 20)</pre>
print(ids)
table(ids)
x \leftarrow sample(c(0, 1), size = 200, replace = TRUE, prob = c(0.05, 0.95))
table(x)
ids <- kfold_split_stratified(K = 5, x = x)</pre>
print(ids)
table(ids, x)
grp \leftarrow gl(n = 50, k = 15, labels = state.name)
length(grp)
head(table(grp))
ids_10 <- kfold_split_grouped(K = 10, x = grp)
(tab_10 <- table(grp, ids_10))
colSums(tab_10)
ids_9 <- kfold_split_grouped(K = 9, x = grp)</pre>
(tab_9 <- table(grp, ids_9))</pre>
colSums(tab_9)
```

100

Efficient approximate leave-one-out cross-validation (LOO)

Description

The loo() methods for arrays, matrices, and functions compute PSIS-LOO CV, efficient approximate leave-one-out (LOO) cross-validation for Bayesian models using Pareto smoothed importance sampling (PSIS). This is an implementation of the methods described in Vehtari, Gelman, and Gabry (2017) and Vehtari, Simpson, Gelman, Yao, and Gabry (2024).

The loo_i() function enables testing log-likelihood functions for use with the loo.function() method.

20 loo

Usage

```
loo(x, ...)
## S3 method for class 'array'
100(
  Х,
  . . . ,
  r_eff = 1,
  save_psis = FALSE,
  cores = getOption("mc.cores", 1),
  is_method = c("psis", "tis", "sis")
)
## S3 method for class 'matrix'
100(
  Х,
  . . . ,
  r_eff = 1,
  save_psis = FALSE,
  cores = getOption("mc.cores", 1),
  is_method = c("psis", "tis", "sis")
)
## S3 method for class '`function`'
100(
  х,
  data = NULL,
  draws = NULL,
  r_{eff} = 1,
  save_psis = FALSE,
  cores = getOption("mc.cores", 1),
  is_method = c("psis", "tis", "sis")
)
loo_i(i, llfun, ..., data = NULL, draws = NULL, r_eff = 1, is_method = "psis")
is.loo(x)
is.psis_loo(x)
```

Arguments

X

A log-likelihood array, matrix, or function. The **Methods** (by class) section, below, has detailed descriptions of how to specify the inputs for each method.

r_eff

Vector of relative effective sample size estimates for the likelihood (exp(log_lik)) of each observation. This is related to the relative efficiency of estimating the normalizing term in self-normalized importance sampling when using poste-

loo 21

rior draws obtained with MCMC. If MCMC draws are used and r_eff is not provided then the reported PSIS effective sample sizes and Monte Carlo error estimates can be over-optimistic. If the posterior draws are (near) independent then r_eff=1 can be used. r_eff has to be a scalar (same value is used for all observations) or a vector with length equal to the number of observations. The default value is 1. See the relative_eff() helper functions for help computing r_eff.

save_psis

Should the psis object created internally by loo() be saved in the returned object? The loo() function calls psis() internally but by default discards the (potentially large) psis object after using it to compute the LOO-CV summaries. Setting save_psis=TRUE will add a psis_object component to the list returned by loo. This is useful if you plan to use the E_loo() function to compute weighted expectations after running loo. Several functions in the bayesplot package also accept psis objects.

cores

The number of cores to use for parallelization. This defaults to the option mc.cores which can be set for an entire R session by options(mc.cores = NUMBER). The old option loo.cores is now deprecated but will be given precedence over mc.cores until loo.cores is removed in a future release. As of version 2.0.0 the default is now 1 core if mc.cores is not set, but we recommend using as many (or close to as many) cores as possible.

• Note for Windows 10 users: it is **strongly** recommended to avoid using the .Rprofile file to set mc.cores (using the cores argument or setting mc.cores interactively or in a script is fine).

is_method

The importance sampling method to use. The following methods are implemented:

- "psis": Pareto-Smoothed Importance Sampling (PSIS). Default method.
- "tis": Truncated Importance Sampling (TIS) with truncation at sqrt(S), where S is the number of posterior draws.
- "sis": Standard Importance Sampling (SIS).

data, draws, ...

For the loo.function() method and the loo_i() function, these are the data, posterior draws, and other arguments to pass to the log-likelihood function. See the **Methods** (**by class**) section below for details on how to specify these arguments.

i For loo_i(), an integer in 1:N.

11fun

For loo_i(), the same as x for the loo.function() method. A log-likelihood function as described in the **Methods** (by class) section.

Details

The loo() function is an S3 generic and methods are provided for 3-D pointwise log-likelihood arrays, pointwise log-likelihood matrices, and log-likelihood functions. The array and matrix methods are the most convenient, but for models fit to very large datasets the loo.function() method is more memory efficient and may be preferable.

Value

The loo() methods return a named list with class c("psis_loo", "loo") and components:

22

estimates A matrix with two columns (Estimate, SE) and three rows (elpd_loo, p_loo, looic). This contains point estimates and standard errors of the expected log pointwise predictive density (elpd_loo), the effective number of parameters (p_loo) and the LOO information criterion looic (which is just -2 * elpd_loo, i.e., converted to deviance scale).

pointwise A matrix with five columns (and number of rows equal to the number of observations) containing the pointwise contributions of the measures (elpd_loo, mcse_elpd_loo, p_loo, looic, influence_pareto_k). in addition to the three measures in estimates, we also report pointwise values of the Monte Carlo standard error of elpd_loo (mcse_elpd_loo), and statistics describing the influence of each observation on the posterior distribution (influence_pareto_k). These are the estimates of the shape parameter k of the generalized Pareto fit to the importance ratios for each leave-one-out distribution (see the pareto-k-diagnostic page for details).

diagnostics A named list containing two vectors:

- pareto_k: Importance sampling reliability diagnostics. By default, these are equal to the influence_pareto_k in pointwise. Some algorithms can improve importance sampling reliability and modify these diagnostics. See the pareto-k-diagnostic page for details.
- n_eff: PSIS effective sample size estimates.

psis_object This component will be NULL unless the save_psis argument is set to TRUE when calling loo(). In that case psis_object will be the object of class "psis" that is created when the loo() function calls psis() internally to do the PSIS procedure.

The loo_i() function returns a named list with components pointwise and diagnostics. These components have the same structure as the pointwise and diagnostics components of the object returned by loo() except they contain results for only a single observation.

Methods (by class)

- loo(array): An I by C by N array, where I is the number of MCMC iterations per chain, C is the number of chains, and N is the number of data points.
- loo(matrix): An S by N matrix, where S is the size of the posterior sample (with all chains merged) and N is the number of data points.
- loo(`function`): A function f() that takes arguments data_i and draws and returns a vector containing the log-likelihood for a single observation i evaluated at each posterior draw. The function should be written such that, for each observation i in 1:N, evaluating

```
f(data_i = data[i,, drop=FALSE], draws = draws)
```

results in a vector of length S (size of posterior sample). The log-likelihood function can also have additional arguments but data_i and draws are required.

If using the function method then the arguments data and draws must also be specified in the call to loo():

- data: A data frame or matrix containing the data (e.g. observed outcome and predictors) needed to compute the pointwise log-likelihood. For each observation i, the ith row of data will be passed to the data_i argument of the log-likelihood function.
- draws: An object containing the posterior draws for any parameters needed to compute
 the pointwise log-likelihood. Unlike data, which is indexed by observation, for each
 observation the entire object draws will be passed to the draws argument of the loglikelihood function.

100

- The ... can be used if your log-likelihood function takes additional arguments. These arguments are used like the draws argument in that they are recycled for each observation.

Defining loo() methods in a package

Package developers can define loo() methods for fitted models objects. See the example loo.stanfit() method in the **Examples** section below for an example of defining a method that calls loo.array(). The loo.stanreg() method in the **rstanarm** package is an example of defining a method that calls loo.function().

Examples

```
### Array and matrix methods (using example objects included with loo package)
# Array method
LLarr <- example_loglik_array()</pre>
rel_n_eff <- relative_eff(exp(LLarr))</pre>
loo(LLarr, r_eff = rel_n_eff, cores = 2)
# Matrix method
LLmat <- example_loglik_matrix()</pre>
rel_n_eff <- relative_eff(exp(LLmat), chain_id = rep(1:2, each = 500))
loo(LLmat, r_eff = rel_n_eff, cores = 2)
### Using log-likelihood function instead of array or matrix
set.seed(124)
# Simulate data and draw from posterior
N <- 50; K <- 10; S <- 100; a0 <- 3; b0 <- 2
p <- rbeta(1, a0, b0)</pre>
y <- rbinom(N, size = K, prob = p)
a <- a0 + sum(y); b <- b0 + N * K - sum(y)
fake_posterior <- as.matrix(rbeta(S, a, b))</pre>
```

24

```
dim(fake_posterior) # S x 1
fake_data <- data.frame(y,K)</pre>
dim(fake_data) # N x 2
llfun <- function(data_i, draws) {</pre>
  # each time called internally within loo the arguments will be equal to:
  # data_i: ith row of fake_data (fake_data[i,, drop=FALSE])
  # draws: entire fake_posterior matrix
  dbinom(data_i$y, size = data_i$K, prob = draws, log = TRUE)
}
# Use the loo_i function to check that llfun works on a single observation
# before running on all obs. For example, using the 3rd obs in the data:
loo_3 <- loo_i(i = 3, llfun = llfun, data = fake_data, draws = fake_posterior)</pre>
print(loo_3$pointwise[, "elpd_loo"])
# Use loo.function method (default r_eff=1 is used as this posterior not obtained via MCMC)
loo_with_fn <- loo(llfun, draws = fake_posterior, data = fake_data)</pre>
# If we look at the elpd_loo contribution from the 3rd obs it should be the
# same as what we got above with the loo_i function and i=3:
print(loo_with_fn$pointwise[3, "elpd_loo"])
print(loo_3$pointwise[, "elpd_loo"])
# Check that the loo.matrix method gives same answer as loo.function method
log_lik_matrix <- sapply(1:N, function(i) {</pre>
  llfun(data_i = fake_data[i,, drop=FALSE], draws = fake_posterior)
})
loo_with_mat <- loo(log_lik_matrix)</pre>
all.equal(loo_with_mat$estimates, loo_with_fn$estimates) # should be TRUE!
## Not run:
### For package developers: defining loo methods
# An example of a possible loo method for 'stanfit' objects (rstan package).
# A similar method is included in the rstan package.
# In order for users to be able to call loo(stanfit) instead of
# loo.stanfit(stanfit) the NAMESPACE needs to be handled appropriately
# (roxygen2 and devtools packages are good for that).
loo.stanfit <-
 function(x,
         pars = "log_lik",
         save_psis = FALSE,
         cores = getOption("mc.cores", 1)) {
  stopifnot(length(pars) == 1L)
  LLarray <- loo::extract_log_lik(stanfit = x,</pre>
                                   parameter_name = pars,
                                   merge_chains = FALSE)
  r_eff <- loo::relative_eff(x = exp(LLarray), cores = cores)
  loo::loo.array(LLarray,
```

loo-datasets 25

loo-datasets

Datasets for loo examples and vignettes

Description

Small datasets for use in **loo** examples and vignettes. The Kline and milk datasets are also included in the **rethinking** package (McElreath, 2016a), but we include them here as **rethinking** is not on CRAN.

Details

Currently the data sets included are:

- Kline: Small dataset from Kline and Boyd (2010) on tool complexity and demography in Oceanic islands societies. This data is discussed in detail in McElreath (2016a,2016b). (Link to variable descriptions)
- milk: Small dataset from Hinde and Milligan (2011) on primate milk composition. This data is discussed in detail in McElreath (2016a, 2016b). (Link to variable descriptions)
- voice: Voice rehabilitation data from Tsanas et al. (2014).

str(milk)
```

26 loo-glossary

loo-glossary LOO package glossary

Description

The pages provides definitions to key terms. Also see the FAQ page on the **loo** website for answers to frequently asked questions.

Note: VGG2017 refers to Vehtari, Gelman, and Gabry (2017). See References, below.

ELPD and elpd_loo

The ELPD is the theoretical expected log pointwise predictive density for a new dataset (Eq 1 in VGG2017), which can be estimated, e.g., using cross-validation. elpd_loo is the Bayesian LOO estimate of the expected log pointwise predictive density (Eq 4 in VGG2017) and is a sum of N individual pointwise log predictive densities. Probability densities can be smaller or larger than 1, and thus log predictive densities can be negative or positive. For simplicity the ELPD acronym is used also for expected log pointwise predictive probabilities for discrete models. Probabilities are always equal or less than 1, and thus log predictive probabilities are 0 or negative.

Standard error of elpd_loo

As elpd_loo is defined as the sum of N independent components (Eq 4 in VGG2017), we can compute the standard error by using the standard deviation of the N components and multiplying by sqrt(N) (Eq 23 in VGG2017). This standard error is a coarse description of our uncertainty about the predictive performance for unknown future data. When N is small or there is severe model misspecification, the current SE estimate is overoptimistic and the actual SE can even be twice as large. Even for moderate N, when the SE estimate is an accurate estimate for the scale, it ignores the skewness. When making model comparisons, the SE of the component-wise (pairwise) differences should be used instead (see the se_diff section below and Eq 24 in VGG2017). Sivula et al. (2022) discuss the conditions when the normal approximation used for SE and se_diff is good.

Monte Carlo SE of elpd_loo

The Monte Carlo standard error is the estimate for the computational accuracy of MCMC and importance sampling used to compute elpd_loo. Usually this is negligible compared to the standard describing the uncertainty due to finite number of observations (Eq 23 in VGG2017).

p_loo (effective number of parameters)

p_loo is the difference between elpd_loo and the non-cross-validated log posterior predictive density. It describes how much more difficult it is to predict future data than the observed data. Asymptotically under certain regularity conditions, p_loo can be interpreted as the *effective number of parameters*. In well behaving cases p_loo < N and p_loo < p, where p is the total number of parameters in the model. p_loo > N or p_loo > p indicates that the model has very weak predictive capability and may indicate a severe model misspecification. See below for more on interpreting p_loo when there are warnings about high Pareto k diagnostic values.

loo-glossary 27

Pareto k estimates

The Pareto k estimate is a diagnostic for Pareto smoothed importance sampling (PSIS), which is used to compute components of elpd_loo. In importance-sampling LOO the full posterior distribution is used as the proposal distribution. The Pareto k diagnostic estimates how far an individual leave-one-out distribution is from the full distribution. If leaving out an observation changes the posterior too much then importance sampling is not able to give a reliable estimate. Pareto smoothing stabilizes importance sampling and guarantees a finite variance estimate at the cost of some bias.

The diagnostic threshold for Pareto k depends on sample size S (sample size dependent threshold was introduced by Vehtari et al., 2024, and before that fixed thresholds of 0.5 and 0.7 were recommended). For simplicity, 100 package uses the nominal sample size S when computing the sample size specific threshold. This provides an optimistic threshold if the effective sample size is less than 2200, but even then if ESS/S > 1/2 the difference is usually negligible. Thinning of MCMC draws can be used to improve the ratio ESS/S.

- If $k < \min(1 1/\log_{10}(S), 0.7)$, where S is the sample size, the PSIS estimate and the corresponding Monte Carlo standard error estimate are reliable.
- If $1-1/\log_{10}(S) <= k < 0.7$, the PSIS estimate and the corresponding Monte Carlo standard error estimate are not reliable, but increasing the (effective) sample size S above 2200 may help (this will increase the sample size specific threshold $(1-1/\log_{10}(2200)>0.7)$ and then the bias specific threshold 0.7 dominates).
- If 0.7 <= k < 1, the PSIS estimate and the corresponding Monte Carlo standard error have large bias and are not reliable. Increasing the sample size may reduce the variability in the k estimate, which may also result in a lower k estimate.
- If k ≥ 1, the target distribution is estimated to have non-finite mean. The PSIS estimate and
 the corresponding Monte Carlo standard error are not well defined. Increasing the sample size
 may reduce the variability in k estimate, which may also result in a lower k estimate.

Pareto k is also useful as a measure of influence of an observation. Highly influential observations have high k values. Very high k values often indicate model misspecification, outliers or mistakes in data processing. See Section 6 of Gabry et al. (2019) for an example.

Interpreting p_loo when Pareto k is large: If k > 0.7 then we can also look at the p_loo estimate for some additional information about the problem:

- If p_loo << p (the total number of parameters in the model), then the model is likely to be misspecified. Posterior predictive checks (PPCs) are then likely to also detect the problem. Try using an overdispersed model, or add more structural information (nonlinearity, mixture model, etc.).
- If p_loo N/5), it is likely that the model is so flexible or the population prior so weak that it's difficult to predict the left out observation (even for the true model). This happens, for example, in the simulated 8 schools (in VGG2017), random effect models with a few observations per random effect, and Gaussian processes and spatial models with short correlation lengths.
- If p_loo > p, then the model is likely to be badly misspecified. If the number of parameters p<<N, then PPCs are also likely to detect the problem. See the case study at https://avehtari.github.io/modelselection/roaches.html for an example. If p is relatively

large compared to the number of observations, say p>N/5 (more accurately we should count number of observations influencing each parameter as in hierarchical models some groups may have few observations and other groups many), it is possible that PPCs won't detect the problem.

elpd_diff

elpd_diff is the difference in elpd_loo for two models. If more than two models are compared, the difference is computed relative to the model with highest elpd_loo.

se diff

The standard error of component-wise differences of elpd_loo (Eq 24 in VGG2017) between two models. This SE is *smaller* than the SE for individual models due to correlation (i.e., if some observations are easier and some more difficult to predict for all models).

loo_approximate_posterior

Efficient approximate leave-one-out cross-validation (LOO) for posterior approximations

Description

Efficient approximate leave-one-out cross-validation (LOO) for posterior approximations

Usage

```
loo_approximate_posterior(x, log_p, log_g, ...)
## S3 method for class 'array'
loo_approximate_posterior(
    x,
    log_p,
    log_g,
```

```
save_psis = FALSE,
  cores = getOption("mc.cores", 1)
)
## S3 method for class 'matrix'
loo_approximate_posterior(
 log_p,
 log_g,
  save_psis = FALSE,
  cores = getOption("mc.cores", 1)
)
## S3 method for class '`function`'
loo_approximate_posterior(
  Х,
  . . . ,
  data = NULL,
  draws = NULL,
 log_p = NULL,
 log_g = NULL,
  save_psis = FALSE,
  cores = getOption("mc.cores", 1)
)
```

Arguments

Χ

A log-likelihood array, matrix, or function. The **Methods** (by class) section, below, has detailed descriptions of how to specify the inputs for each method.

log_p

The log-posterior (target) evaluated at S samples from the proposal distribution (g). A vector of length S.

log_g

The log-density (proposal) evaluated at S samples from the proposal distribution (g). A vector of length S.

save_psis

Should the "psis" object created internally by loo_approximate_posterior() be saved in the returned object? See loo() for details.

cores

The number of cores to use for parallelization. This defaults to the option mc.cores which can be set for an entire R session by options(mc.cores = NUMBER). The old option loo.cores is now deprecated but will be given precedence over mc.cores until loo.cores is removed in a future release. As of version 2.0.0 the default is now 1 core if mc.cores is not set, but we recommend using as many (or close to as many) cores as possible.

• Note for Windows 10 users: it is **strongly** recommended to avoid using the .Rprofile file to set mc.cores (using the cores argument or setting mc.cores interactively or in a script is fine).

data, draws, ... For the loo_approximate_posterior.function() method, these are the data, posterior draws, and other arguments to pass to the log-likelihood function. See the **Methods (by class)** section below for details on how to specify these arguments.

Details

The loo_approximate_posterior() function is an S3 generic and methods are provided for 3-D pointwise log-likelihood arrays, pointwise log-likelihood matrices, and log-likelihood functions. The implementation works for posterior approximations where it is possible to compute the log density for the posterior approximation.

Value

The loo_approximate_posterior() methods return a named list with class c("psis_loo_ap", "psis_loo", "loo"). It has the same structure as the objects returned by loo() but with the additional slot:

posterior_approximation A list with two vectors, log_p and log_g of the same length containing the posterior density and the approximation density for the individual draws.

Methods (by class)

- loo_approximate_posterior(array): An I by C by N array, where I is the number of MCMC iterations per chain, C is the number of chains, and N is the number of data points.
- loo_approximate_posterior(matrix): An S by N matrix, where S is the size of the posterior sample (with all chains merged) and N is the number of data points.
- loo_approximate_posterior(`function`): A function f() that takes arguments data_i and draws and returns a vector containing the log-likelihood for a single observation i evaluated at each posterior draw. The function should be written such that, for each observation i in 1:N, evaluating

```
f(data_i = data[i,, drop=FALSE], draws = draws)
```

results in a vector of length S (size of posterior sample). The log-likelihood function can also have additional arguments but data_i and draws are required.

If using the function method then the arguments data and draws must also be specified in the call to loo():

- data: A data frame or matrix containing the data (e.g. observed outcome and predictors) needed to compute the pointwise log-likelihood. For each observation i, the ith row of data will be passed to the data_i argument of the log-likelihood function.
- draws: An object containing the posterior draws for any parameters needed to compute
 the pointwise log-likelihood. Unlike data, which is indexed by observation, for each
 observation the entire object draws will be passed to the draws argument of the loglikelihood function.
- The ... can be used if your log-likelihood function takes additional arguments. These
 arguments are used like the draws argument in that they are recycled for each observation.

loo_compare 31

loo_compare

Model comparison

Description

Compare fitted models based on ELPD.

By default the print method shows only the most important information. Use print(..., simplify=FALSE) to print a more detailed summary.

Usage

```
loo_compare(x, ...)
## Default S3 method:
loo_compare(x, ...)
## S3 method for class 'compare.loo'
print(x, ..., digits = 1, simplify = TRUE)
## S3 method for class 'compare.loo_ss'
print(x, ..., digits = 1, simplify = TRUE)
```

Arguments

Х	An object of class "loo" or a list of such objects. If a list is used then the list names will be used as the model names in the output. See Examples .
	Additional objects of class "loo", if not passed in as a single list.
digits	For the print method only, the number of digits to use when printing.
simplify	For the print method only, should only the essential columns of the summary matrix be printed? The entire matrix is always returned, but by default only the most important columns are printed.

32 loo_compare

Details

When comparing two fitted models, we can estimate the difference in their expected predictive accuracy by the difference in elpd_loo or elpd_waic (or multiplied by -2, if desired, to be on the deviance scale).

When using loo_compare(), the returned matrix will have one row per model and several columns of estimates. The values in the elpd_diff and se_diff columns of the returned matrix are computed by making pairwise comparisons between each model and the model with the largest ELPD (the model in the first row). For this reason the elpd_diff column will always have the value 0 in the first row (i.e., the difference between the preferred model and itself) and negative values in subsequent rows for the remaining models.

To compute the standard error of the difference in ELPD — which should not be expected to equal the difference of the standard errors — we use a paired estimate to take advantage of the fact that the same set of N data points was used to fit both models. These calculations should be most useful when N is large, because then non-normality of the distribution is not such an issue when estimating the uncertainty in these sums. These standard errors, for all their flaws, should give a better sense of uncertainty than what is obtained using the current standard approach of comparing differences of deviances to a Chi-squared distribution, a practice derived for Gaussian linear models or asymptotically, and which only applies to nested models in any case. Sivula et al. (2022) discuss the conditions when the normal approximation used for SE and se_diff is good.

If more than 11 models are compared, we internally recompute the model differences using the median model by ELPD as the baseline model. We then estimate whether the differences in predictive performance are potentially due to chance as described by McLatchie and Vehtari (2023). This will flag a warning if it is deemed that there is a risk of over-fitting due to the selection process. In that case users are recommended to avoid model selection based on LOO-CV, and instead to favor model averaging/stacking or projection predictive inference.

Value

A matrix with class "compare.loo" that has its own print method. See the **Details** section.

```
# very artificial example, just for demonstration!
LL <- example_loglik_array()</pre>
loo1 <- loo(LL)
                   # should be worst model when compared
loo2 <- loo(LL + 1) # should be second best model when compared</pre>
loo3 <- loo(LL + 2) # should be best model when compared</pre>
comp <- loo_compare(loo1, loo2, loo3)</pre>
print(comp, digits = 2)
# show more details with simplify=FALSE
# (will be the same for all models in this artificial example)
print(comp, simplify = FALSE, digits = 3)
# can use a list of objects with custom names
# will use apple, banana, and cherry, as the names in the output
loo_compare(list("apple" = loo1, "banana" = loo2, "cherry" = loo3))
## Not run:
# works for waic (and kfold) too
loo_compare(waic(LL), waic(LL - 10))
## End(Not run)
```

loo_model_weights

Model averaging/weighting via stacking or pseudo-BMA weighting

Description

Model averaging via stacking of predictive distributions, pseudo-BMA weighting or pseudo-BMA+ weighting with the Bayesian bootstrap. See Yao et al. (2018), Vehtari, Gelman, and Gabry (2017), and Vehtari, Simpson, Gelman, Yao, and Gabry (2024) for background.

Usage

```
loo_model_weights(x, ...)
## Default S3 method:
loo_model_weights(
    x,
    ...,
    method = c("stacking", "pseudobma"),
    optim_method = "BFGS",
    optim_control = list(),
    BB = TRUE,
    BB_n = 1000,
    alpha = 1,
```

```
r_eff_list = NULL,
 cores = getOption("mc.cores", 1)
)
stacking_weights(lpd_point, optim_method = "BFGS", optim_control = list())
pseudobma_weights(lpd_point, BB = TRUE, BB_n = 1000, alpha = 1)
```

Arguments

Х

A list of "psis_loo" objects (objects returned by loo()) or pointwise loglikelihood matrices or, one for each model. If the list elements are named the names will be used to label the models in the results. Each matrix/object should have dimensions S by N, where S is the size of the posterior sample (with all chains merged) and N is the number of data points. If x is a list of loglikelihood matrices then loo() is called internally on each matrix. Currently the loo_model_weights() function is not implemented to be used with results from K-fold CV, but you can still obtain weights using K-fold CV results by calling the stacking_weights() function directly.

Unused, except for the generic to pass arguments to individual methods.

method

Either "stacking" (the default) or "pseudobma", indicating which method to use for obtaining the weights. "stacking" refers to stacking of predictive distributions and "pseudobma" refers to pseudo-BMA+ weighting (or plain pseudo-BMA weighting if argument BB is FALSE).

optim_method

If method="stacking", a string passed to the method argument of stats::constrOptim() to specify the optimization algorithm. The default is optim_method="BFGS", but other options are available (see stats::optim()).

optim_control

If method="stacking", a list of control parameters for optimization passed to

the control argument of stats::constrOptim().

BB

Logical used when "method"="pseudobma". If TRUE (the default), the Bayesian bootstrap will be used to adjust the pseudo-BMA weighting, which is called pseudo-BMA+ weighting. It helps regularize the weight away from 0 and 1, so as to reduce the variance.

BB_n

For pseudo-BMA+ weighting only, the number of samples to use for the Bayesian bootstrap. The default is BB_n=1000.

alpha

Positive scalar shape parameter in the Dirichlet distribution used for the Bayesian bootstrap. The default is alpha=1, which corresponds to a uniform distribution on the simplex space.

r_eff_list

Optionally, a list of relative effective sample size estimates for the likelihood (exp(log_lik)) of each observation in each model. See psis() and relative_eff() helper function for computing r_eff. If x is a list of "psis_loo" objects then r_eff_list is ignored.

cores

The number of cores to use for parallelization. This defaults to the option mc.cores which can be set for an entire R session by options(mc.cores =NUMBER). The old option loo.cores is now deprecated but will be given precedence over mc. cores until loo. cores is removed in a future release. As of

version 2.0.0 the default is now 1 core if mc.cores is not set, but we recommend using as many (or close to as many) cores as possible.

• Note for Windows 10 users: it is **strongly** recommended to avoid using the .Rprofile file to set mc.cores (using the cores argument or setting mc.cores interactively or in a script is fine).

lpd_point

If calling stacking_weights() or pseudobma_weights() directly, a matrix of pointwise leave-one-out (or K-fold) log likelihoods evaluated for different models. It should be a N by K matrix where N is sample size and K is the number of models. Each column corresponds to one model. These values can be calculated approximately using loo() or by running exact leave-one-out or K-fold cross-validation.

Details

loo_model_weights() is a wrapper around the stacking_weights() and pseudobma_weights() functions that implements stacking, pseudo-BMA, and pseudo-BMA+ weighting for combining multiple predictive distributions. We can use approximate or exact leave-one-out cross-validation (LOO-CV) or K-fold CV to estimate the expected log predictive density (ELPD).

The stacking method (method="stacking"), which is the default for loo_model_weights(), combines all models by maximizing the leave-one-out predictive density of the combination distribution. That is, it finds the optimal linear combining weights for maximizing the leave-one-out log score.

The pseudo-BMA method (method="pseudobma") finds the relative weights proportional to the ELPD of each model. However, when method="pseudobma", the default is to also use the Bayesian bootstrap (BB=TRUE), which corresponds to the pseudo-BMA+ method. The Bayesian bootstrap takes into account the uncertainty of finite data points and regularizes the weights away from the extremes of 0 and 1.

In general, we recommend stacking for averaging predictive distributions, while pseudo-BMA+ can serve as a computationally easier alternative.

Value

A numeric vector containing one weight for each model.

loo_moment_match

Moment matching for efficient approximate leave-one-out cross-validation (LOO)

Description

Moment matching algorithm for updating a loo object when Pareto k estimates are large.

Usage

```
loo_moment_match(x, ...)
## Default S3 method:
```

38 loo_moment_match

```
loo_moment_match(
    x,
    loo,
    post_draws,
    log_lik_i,
    unconstrain_pars,
    log_prob_upars,
    log_lik_i_upars,
    max_iters = 30L,
    k_threshold = NULL,
    split = TRUE,
    cov = TRUE,
    cores = getOption("mc.cores", 1),
    ...
)
```

Arguments

x A fitted model object.

... Further arguments passed to the custom functions documented above.

loo A loo object to be modified.

post_draws A function the takes x as the first argument and returns a matrix of posterior

draws of the model parameters.

log_lik_i A function that takes x and i and returns a matrix (one column per chain) or a vector (all chains stacked) of log-likelihood draws of the ith observation based

on the model x. If the draws are obtained using MCMC, the matrix with MCMC

chains separated is preferred.

unconstrain_pars

A function that takes arguments x, and pars and returns posterior draws on the unconstrained space based on the posterior draws on the constrained space

passed via pars.

log_prob_upars A function that takes arguments x and upars and returns a matrix of log-posterior

density values of the unconstrained posterior draws passed via upars.

log_lik_i_upars

A function that takes arguments x, upars, and i and returns a vector of log-likelihood draws of the ith observation based on the unconstrained posterior

draws passed via upars.

max_iters Maximum number of moment matching iterations. Usually this does not need

to be modified. If the maximum number of iterations is reached, there will be a

warning, and increasing max_iters may improve accuracy.

k_threshold Threshold value for Pareto k values above which the moment matching algo-

rithm is used. The default value is 1 - 1 / log10(S), where S is the sample

size.

split Logical; Indicate whether to do the split transformation or not at the end of

moment matching for each LOO fold.

loo_moment_match 39

cov

Logical; Indicate whether to match the covariance matrix of the samples or not. If FALSE, only the mean and marginal variances are matched.

cores

The number of cores to use for parallelization. This defaults to the option mc.cores which can be set for an entire R session by options(mc.cores = NUMBER). The old option loo.cores is now deprecated but will be given precedence over mc.cores until loo.cores is removed in a future release. As of version 2.0.0 the default is now 1 core if mc.cores is not set, but we recommend using as many (or close to as many) cores as possible.

• Note for Windows 10 users: it is **strongly** recommended to avoid using the .Rprofile file to set mc.cores (using the cores argument or setting mc.cores interactively or in a script is fine).

Details

The loo_moment_match() function is an S3 generic and we provide a default method that takes as arguments user-specified functions post_draws, log_lik_i, unconstrain_pars, log_prob_upars, and log_lik_i_upars. All of these functions should take as an argument in addition to those specified for each function.

Value

The loo_moment_match() methods return an updated loo object. The structure of the updated loo object is similar, but the method also stores the original Pareto k diagnostic values in the diagnostics field.

Methods (by class)

• loo_moment_match(default): A default method that takes as arguments a user-specified model object x, a loo object and user-specified functions post_draws, log_lik_i, unconstrain_pars, log_prob_upars, and log_lik_i_upars.

loo_moment_match_split
```

Split moment matching for efficient approximate leave-one-out cross-validation (LOO)

Description

A function that computes the split moment matching importance sampling loo. Takes in the moment matching total transformation, transforms only half of the draws, and computes a single elpd using multiple importance sampling.

Usage

```
loo_moment_match_split(
    x,
    upars,
    cov,
    total_shift,
    total_scaling,
    total_mapping,
    i,
    log_prob_upars,
    log_lik_i_upars,
    r_eff_i,
    cores,
    is_method,
    ...
)
```

Arguments

x	A fitted model object.
upars	A matrix containing the model parameters in unconstrained space where they can have any real value.
COV	Logical; Indicate whether to match the covariance matrix of the samples or not. If FALSE, only the mean and marginal variances are matched.
total_shift	A vector representing the total shift made by the moment matching algorithm.
total_scaling	A vector representing the total scaling of marginal variance made by the moment matching algorithm.
total_mapping	A vector representing the total covariance transformation made by the moment matching algorithm.
i	Observation index.
log_prob_upars	A function that takes arguments x and upars and returns a matrix of log-posterior density values of the unconstrained posterior draws passed via upars.

loo_predictive_metric

log_lik_i_upars

A function that takes arguments x, upars, and i and returns a vector of loglikeliood draws of the ith observation based on the unconstrained posterior draws passed via upars.

41

r_eff_i cores

MCMC relative effective sample size of the i'th log likelihood draws.

The number of cores to use for parallelization. This defaults to the option mc.cores which can be set for an entire R session by options(mc.cores =NUMBER). The old option loo.cores is now deprecated but will be given precedence over mc. cores until loo. cores is removed in a future release. As of version 2.0.0 the default is now 1 core if mc. cores is not set, but we recommend using as many (or close to as many) cores as possible.

• Note for Windows 10 users: it is **strongly** recommended to avoid using the .Rprofile file to set mc.cores (using the cores argument or setting mc. cores interactively or in a script is fine).

is_method

The importance sampling method to use. The following methods are implemented:

- "psis": Pareto-Smoothed Importance Sampling (PSIS). Default method.
- "tis": Truncated Importance Sampling (TIS) with truncation at sqrt(S), where S is the number of posterior draws.
- "sis": Standard Importance Sampling (SIS).

Further arguments passed to the custom functions documented above.

Value

A list containing the updated log-importance weights and log-likelihood values. Also returns the updated MCMC effective sample size and the integrand-specific log-importance weights.

loo(), loo_moment_match()

loo_predictive_metric Estimate leave-one-out predictive performance..

Description

The loo_predictive_metric() function computes estimates of leave-one-out predictive metrics given a set of predictions and observations. Currently supported metrics are mean absolute error, mean squared error and root mean squared error for continuous predictions and accuracy and balanced accuracy for binary classification. Predictions are passed on to the E_loo() function, so this function assumes that the PSIS approximation is working well.

Usage

```
loo_predictive_metric(x, ...)

## S3 method for class 'matrix'
loo_predictive_metric(
    x,
    y,
    log_lik,
    ...,
    metric = c("mae", "rmse", "mse", "acc", "balanced_acc"),
    r_eff = 1,
    cores = getOption("mc.cores", 1)
)
```

Arguments

x	A numeric matrix of predictions.	
	Additional arguments passed on to E_loo()	
у	A numeric vector of observations. Length should be equal to the number of rows in x.	
log_lik	A matrix of pointwise log-likelihoods. Should be of same dimension as x.	
metric	The type of predictive metric to be used. Currently supported options are "mae", "rmse" and "mse" for regression and for binary classification "acc" and "balanced_acc"	
	"mae" Mean absolute error.	
	"mse" Mean squared error.	
	"rmse" Root mean squared error, given by as the square root of MSE.	
	"acc" The proportion of predictions indicating the correct outcome.	
	"balanced_acc" Balanced accuracy is given by the average of true positive and true negative rates.	
r_eff	A Vector of relative effective sample size estimates containing one element per observation. See psis() for more details.	
cores	The number of cores to use for parallelization of [psis()]. See psis() for details.	

Value

A list with the following components:

estimate Estimate of the given metric. se Standard error of the estimate.

Examples

```
if (requireNamespace("rstanarm", quietly = TRUE)) {
# Use rstanarm package to quickly fit a model and get both a log-likelihood
# matrix and draws from the posterior predictive distribution
```

```
library("rstanarm")
# data from help("lm")
ctl \leftarrow c(4.17, 5.58, 5.18, 6.11, 4.50, 4.61, 5.17, 4.53, 5.33, 5.14)
trt < c(4.81, 4.17, 4.41, 3.59, 5.87, 3.83, 6.03, 4.89, 4.32, 4.69)
d <- data.frame(</pre>
  weight = c(ctl, trt),
  group = gl(2, 10, 20, labels = c("Ctl","Trt"))
fit <- stan_glm(weight ~ group, data = d, refresh = 0)</pre>
ll <- log_lik(fit)</pre>
r_eff <- relative_eff(exp(-ll), chain_id = rep(1:4, each = 1000))
mu_pred <- posterior_epred(fit)</pre>
# Leave-one-out mean absolute error of predictions
mae <- loo_predictive_metric(x = mu_pred, y = d$weight, log_lik = 11,</pre>
                              pred_error = 'mae', r_eff = r_eff)
# Leave-one-out 90%-quantile of mean absolute error
mae_90q <- loo_predictive_metric(x = mu_pred, y = d$weight, log_lik = ll,</pre>
                                   pred_error = 'mae', r_eff = r_eff,
                                   type = 'quantile', probs = 0.9)
}
```

loo_subsample

Efficient approximate leave-one-out cross-validation (LOO) using subsampling, so that less costly and more approximate computation is made for all LOO-fold, and more costly and accurate computations are made only for m<N LOO-folds.

Description

Efficient approximate leave-one-out cross-validation (LOO) using subsampling, so that less costly and more approximate computation is made for all LOO-fold, and more costly and accurate computations are made only for m<N LOO-folds.

Usage

```
loo_subsample(x, ...)
## S3 method for class '`function`'
loo_subsample(
    x,
    ...,
    data = NULL,
    draws = NULL,
    observations = 400,
    log_p = NULL,
    log_g = NULL,
```

```
r_eff = 1,
  save_psis = FALSE,
  cores = getOption("mc.cores", 1),
  loo_approximation = "plpd",
  loo_approximation_draws = NULL,
  estimator = "diff_srs",
 11grad = NULL,
 11hess = NULL
)
```

Arguments

Х

A function. The **Methods** (by class) section, below, has detailed descriptions of how to specify the inputs.

data, draws, ...

For loo_subsample.function(), these are the data, posterior draws, and other arguments to pass to the log-likelihood function. Note that for some loo_approximations, the draws will be replaced by the posteriors summary statistics to compute loo approximations. See argument loo_approximation for details.

observations

The subsample observations to use. The argument can take four (4) types of arguments:

- NULL to use all observations. The algorithm then just uses standard loo() or loo_approximate_posterior().
- A single integer to specify the number of observations to be subsampled.
- A vector of integers to provide the indices used to subset the data. These observations need to be subsampled with the same scheme as given by the estimator argument.
- A psis_loo_ss object to use the same observations that were used in a previous call to loo_subsample().

log_p, log_g

Should be supplied only if approximate posterior draws are used. The default (NULL) indicates draws are from "true" posterior (i.e. using MCMC). If not NULL then they should be specified as described in loo_approximate_posterior().

r_eff

Vector of relative effective sample size estimates for the likelihood (exp(log_lik)) of each observation. This is related to the relative efficiency of estimating the normalizing term in self-normalized importance sampling when using posterior draws obtained with MCMC. If MCMC draws are used and r_eff is not provided then the reported PSIS effective sample sizes and Monte Carlo error estimates can be over-optimistic. If the posterior draws are (near) independent then r_eff=1 can be used. r_eff has to be a scalar (same value is used for all observations) or a vector with length equal to the number of observations. The default value is 1. See the relative_eff() helper functions for help computing

save_psis

Should the "psis" object created internally by loo_subsample() be saved in the returned object? See loo() for details.

cores

The number of cores to use for parallelization. This defaults to the option mc.cores which can be set for an entire R session by options(mc.cores =NUMBER). The old option loo.cores is now deprecated but will be given precedence over mc. cores until loo. cores is removed in a future release. As of

version 2.0.0 the default is now 1 core if mc. cores is not set, but we recommend using as many (or close to as many) cores as possible.

• Note for Windows 10 users: it is **strongly** recommended to avoid using the .Rprofile file to set mc.cores (using the cores argument or setting mc.cores interactively or in a script is fine).

loo_approximation

What type of approximation of the loo_i's should be used? The default is "plpd" (the log predictive density using the posterior expectation). There are six different methods implemented to approximate loo_i's (see the references for more details):

- "plpd": uses the lpd based on point estimates (i.e., $p(y_i|\hat{\theta})$).
- "lpd": uses the lpds (i,e., $p(y_i|y)$).
- "tis": uses truncated importance sampling to approximate PSIS-LOO.
- "waic": uses waic (i.e., $p(y_i|y) p_{waic}$).
- "waic_grad_marginal": uses waic approximation using first order delta method and posterior marginal variances to approximate p_{waic} (ie. $p(y_i|\hat{\theta})$ -p_waic_grad_marginal). Requires gradient of likelihood function.
- "waic_grad": uses waic approximation using first order delta method and posterior covariance to approximate p_{waic} (ie. $p(y_i|\hat{\theta})$ -p_waic_grad). Requires gradient of likelihood function.
- "waic_hess": uses waic approximation using second order delta method and posterior covariance to approximate p_{waic} (ie. $p(y_i|\hat{\theta})$ -p_waic_grad). Requires gradient and Hessian of likelihood function.

As point estimates of $\hat{\theta}$, the posterior expectations of the parameters are used.

loo_approximation_draws

The number of posterior draws used when integrating over the posterior. This is used if loo_approximation is set to "lpd", "waic", or "tis".

estimator

How should elpd_loo, p_loo and looic be estimated? The default is "diff_srs".

- "diff_srs": uses the difference estimator with simple random sampling without replacement (srs). p_loo is estimated using standard srs. (Magnusson et al., 2020)
- "hh": uses the Hansen-Hurwitz estimator with sampling with replacement proportional to size, where abs of loo_approximation is used as size. (Magnusson et al., 2019)
- $\bullet\,$ "srs": uses simple random sampling and ordinary estimation.

llgrad

The gradient of the log-likelihood. This is only used when loo_approximation is "waic_grad", "waic_grad_marginal", or "waic_hess". The default is NULL.

llhess

The Hessian of the log-likelihood. This is only used with loo_approximation = "waic_hess". The default is NULL.

Details

The loo_subsample() function is an S3 generic and a methods is currently provided for log-likelihood functions. The implementation works for both MCMC and for posterior approximations where it is possible to compute the log density for the approximation.

Value

loo_subsample() returns a named list with class c("psis_loo_ss", "psis_loo", "loo"). This has the same structure as objects returned by loo() but with the additional slot:

• loo_subsampling: A list with two vectors, log_p and log_g, of the same length containing the posterior density and the approximation density for the individual draws.

Methods (by class)

• loo_subsample(`function`): A function f() that takes arguments data_i and draws and returns a vector containing the log-likelihood for a single observation i evaluated at each posterior draw. The function should be written such that, for each observation i in 1:N, evaluating

```
f(data_i = data[i,, drop=FALSE], draws = draws)
```

results in a vector of length S (size of posterior sample). The log-likelihood function can also have additional arguments but data_i and draws are required.

If using the function method then the arguments data and draws must also be specified in the call to loo():

- data: A data frame or matrix containing the data (e.g. observed outcome and predictors)
 needed to compute the pointwise log-likelihood. For each observation i, the ith row of data will be passed to the data_i argument of the log-likelihood function.
- draws: An object containing the posterior draws for any parameters needed to compute
 the pointwise log-likelihood. Unlike data, which is indexed by observation, for each
 observation the entire object draws will be passed to the draws argument of the loglikelihood function.
- The ... can be used if your log-likelihood function takes additional arguments. These arguments are used like the draws argument in that they are recycled for each observation.

nobs.psis_loo_ss 47

nobs.psis_loo_ss

The number of observations in a psis_loo_ss object.

Description

The number of observations in a psis_loo_ss object.

Usage

```
## S3 method for class 'psis_loo_ss'
nobs(object, ...)
```

Arguments

object a psis_loo_ss object.
... Currently unused.

 obs_idx

Get observation indices used in subsampling

Description

Get observation indices used in subsampling

Usage

```
obs_idx(x, rep = TRUE)
```

Arguments

x A psis_loo_ss object.

rep If sampling with replacement is used, an observation can have multiple sam-

ples and these are then repeated in the returned object if rep=TRUE (e.g., a vector c(1,1,2) indicates that observation 1 has been subampled two times). If

rep=FALSE only the unique indices are returned.

Value

An integer vector.

48 pareto-k-diagnostic

pareto-k-diagnostic Diagnostics for Pareto smoothed importance sampling (PSIS)

Description

Print a diagnostic table summarizing the estimated Pareto shape parameters and PSIS effective sample sizes, find the indexes of observations for which the estimated Pareto shape parameter k is larger than some threshold value, or plot observation indexes vs. diagnostic estimates. The **Details** section below provides a brief overview of the diagnostics, but we recommend consulting Vehtari, Gelman, and Gabry (2017) and Vehtari, Simpson, Gelman, Yao, and Gabry (2024) for full details.

Usage

```
pareto_k_table(x)
pareto_k_ids(x, threshold = NULL)
pareto_k_values(x)
pareto_k_influence_values(x)
psis_n_eff_values(x)
mcse_{loo}(x, threshold = NULL)
## S3 method for class 'psis_loo'
plot(
 diagnostic = c("k", "ESS", "n_eff"),
  label_points = FALSE,
  main = "PSIS diagnostic plot"
)
## S3 method for class 'psis'
plot(
  diagnostic = c("k", "ESS", "n_eff"),
  label_points = FALSE,
 main = "PSIS diagnostic plot"
)
```

Arguments

An object created by loo() or psis().

pareto-k-diagnostic 49

threshold For pareto_k_ids(), threshold is the minimum k value to flag (default is a

sample size S dependend threshold 1 – 1 / log10(S)). For mcse_loo(), if any k estimates are greater than threshold the MCSE estimate is returned as NA See

Details for the motivation behind these defaults.

diagnostic For the plot method, which diagnostic should be plotted? The options are "k"

for Pareto k estimates (the default), or "ESS" or "n_eff" for PSIS effective

sample size estimates.

label_points, ...

For the plot() method, if label_points is TRUE the observation numbers corresponding to any values of k greater than the diagnostic threshold will be displayed in the plot. Any arguments specified in . . . will be passed to graphics::text()

and can be used to control the appearance of the labels.

main For the plot() method, a title for the plot.

Details

The reliability and approximate convergence rate of the PSIS-based estimates can be assessed using the estimates for the shape parameter k of the generalized Pareto distribution. The diagnostic threshold for Pareto k depends on sample size S (sample size dependent threshold was introduced by Vehtari et al. (2024), and before that fixed thresholds of 0.5 and 0.7 were recommended). For simplicity, 100 package uses the nominal sample size S when computing the sample size specific threshold. This provides an optimistic threshold if the effective sample size is less than 2200, but if MCMC-ESS > S/2 the difference is usually negligible. Thinning of MCMC draws can be used to improve the ratio ESS/S.

- If k < min(1 1/log10(S), 0.7), where S is the sample size, the PSIS estimate and the corresponding Monte Carlo standard error estimate are reliable.
- If 1-1/log10(S) <= k < 0.7, the PSIS estimate and the corresponding Monte Carlo standard error estimate are not reliable, but increasing the (effective) sample size S above 2200 may help (this will increase the sample size specific threshold (1-1/log10(2200)>0.7) and then the bias specific threshold 0.7 dominates).
- If 0.7 <= k < 1, the PSIS estimate and the corresponding Monte Carlo standard error have large bias and are not reliable. Increasing the sample size may reduce the variability in k estimate, which may result in lower k estimate, too.

What if the estimated tail shape parameter k exceeds the diagnostic threshold?: Importance sampling is likely to work less well if the marginal posterior $p(\theta^s|y)$ and LOO posterior $p(\theta^s|y_{-i})$ are very different, which is more likely to happen with a non-robust model and highly influential observations. If the estimated tail shape parameter k exceeds the diagnostic threshold, the user should be warned. (Note: If k is greater than the diagnostic threshold then WAIC is also likely to fail, but WAIC lacks as accurate diagnostic.) When using PSIS in the context of approximate LOO-CV, we recommend one of the following actions:

• With some additional computations, it is possible to transform the MCMC draws from the posterior distribution to obtain more reliable importance sampling estimates. This results in a

50 pareto-k-diagnostic

smaller shape parameter k. See loo_moment_match() and the vignette Avoiding model refits in leave-one-out cross-validation with moment matching for an example of this.

- Sampling from a leave-one-out mixture distribution (see the vignette Mixture IS leave-one-out cross-validation for high-dimensional Bayesian models), directly from $p(\theta^s|y_{-i})$ for the problematic observations i, or using K-fold cross-validation (see the vignette Holdout validation and K-fold cross-validation of Stan programs with the loo package) will generally be more stable.
- Using a model that is more robust to anomalous observations will generally make approximate LOO-CV more stable.

Observation influence statistics: The estimated shape parameter k for each observation can be used as a measure of the observation's influence on posterior distribution of the model. These can be obtained with pareto_k_influence_values().

Effective sample size and error estimates: In the case that we obtain the samples from the proposal distribution via MCMC the **loo** package also computes estimates for the Monte Carlo error and the effective sample size for importance sampling, which are more accurate for PSIS than for IS and TIS (see Vehtari et al (2024) for details). However, the PSIS effective sample size estimate will be **over-optimistic when the estimate of** k **is greater than** min(1-1/log10(S), 0.7), where S is the sample size.

Value

pareto_k_table() returns an object of class "pareto_k_table", which is a matrix with columns "Count", "Proportion", and "Min. n_eff", and has its own print method.

 $pareto_k_ids()$ returns an integer vector indicating which observations have Pareto k estimates above threshold.

pareto_k_values() returns a vector of the estimated Pareto k parameters. These represent the reliability of sampling.

pareto_k_influence_values() returns a vector of the estimated Pareto k parameters. These represent influence of the observations on the model posterior distribution.

psis_n_eff_values() returns a vector of the estimated PSIS effective sample sizes.

 $mcse_loo()$ returns the Monte Carlo standard error (MCSE) estimate for PSIS-LOO. MCSE will be NA if any Pareto k values are above threshold.

The plot() method is called for its side effect and does not return anything. If x is the result of a call to loo() or psis() then plot(x, diagnostic) produces a plot of the estimates of the Pareto shape parameters (diagnostic = "k") or estimates of the PSIS effective sample sizes (diagnostic = "ESS").

pointwise

Convenience function for extracting pointwise estimates

Description

Convenience function for extracting pointwise estimates

Usage

```
pointwise(x, estimate, ...)
## S3 method for class 'loo'
pointwise(x, estimate, ...)
```

Arguments

A loo object, for example one returned by loo(), loo_subsample(), loo_approximate_posterior(), loo_moment_match(), etc.

Which pointwise estimate to return. By default all are returned. The objects returned by the different functions (loo(), loo_subsample(), etc.) have slightly different estimates available. Typically at a minimum the estimates elpd_loo, looic, mcse_elpd_loo, p_loo, and influence_pareto_k will be available, but there may be others.

Value

A vector of length equal to the number of observations.

Currently ignored.

Examples

```
x <- loo(example_loglik_array())
pointwise(x, "elpd_loo")</pre>
```

52 print.loo

print.loo

Print methods

Description

Print methods

Usage

```
## S3 method for class 'loo'
print(x, digits = 1, ...)

## S3 method for class 'waic'
print(x, digits = 1, ...)

## S3 method for class 'psis_loo'
print(x, digits = 1, plot_k = FALSE, ...)

## S3 method for class 'importance_sampling_loo'
print(x, digits = 1, plot_k = FALSE, ...)

## S3 method for class 'psis_loo_ap'
print(x, digits = 1, plot_k = FALSE, ...)

## S3 method for class 'psis'
print(x, digits = 1, plot_k = FALSE, ...)

## S3 method for class 'importance_sampling'
print(x, digits = 1, plot_k = FALSE, ...)
```

Arguments

X	An object returned by loo(), psis(), or waic().
digits	An integer passed to base::round().
	Arguments passed to plot.psis_loo() if plot_k is TRUE.
plot_k	Logical. If TRUE the estimates of the Pareto shape parameter k are plotted. Ignored if x was generated by waic(). To just plot k without printing use the plot() method for 'loo' objects.

Value

x, invisibly.

pareto-k-diagnostic

psis 53

psis

Pareto smoothed importance sampling (PSIS)

Description

Implementation of Pareto smoothed importance sampling (PSIS), a method for stabilizing importance ratios. The version of PSIS implemented here corresponds to the algorithm presented in Vehtari, Simpson, Gelman, Yao, and Gabry (2024). For PSIS diagnostics see the pareto-k-diagnostic page.

Usage

```
psis(log_ratios, ...)
## S3 method for class 'array'
psis(log_ratios, ..., r_eff = 1, cores = getOption("mc.cores", 1))
## S3 method for class 'matrix'
psis(log_ratios, ..., r_eff = 1, cores = getOption("mc.cores", 1))
## Default S3 method:
psis(log_ratios, ..., r_eff = 1)
is.psis(x)
is.tis(x)
```

Arguments

log_ratios

An array, matrix, or vector of importance ratios on the log scale (for PSIS-LOO these are *negative* log-likelihood values). See the **Methods** (**by class**) section below for a detailed description of how to specify the inputs for each method.

Arguments passed on to the various methods.

r_eff

Vector of relative effective sample size estimates containing one element per observation. The values provided should be the relative effective sample sizes of $1/\exp(\log_ratios)$ (i.e., 1/ratios). This is related to the relative efficiency of estimating the normalizing term in self-normalizing importance sampling. If r_eff is not provided then the reported PSIS effective sample sizes and Monte Carlo error estimates can be over-optimistic. If the posterior draws are (near) independent then $r_eff=1$ can be used. r_eff has to be a scalar (same value is used for all observations) or a vector with length equal to the number of observations. The default value is 1. See the $relative_eff()$ helper function for computing r_eff .

54 psis

cores

The number of cores to use for parallelization. This defaults to the option mc.cores which can be set for an entire R session by options(mc.cores = NUMBER). The old option loo.cores is now deprecated but will be given precedence over mc.cores until loo.cores is removed in a future release. As of version 2.0.0 the default is now 1 core if mc.cores is not set, but we recommend using as many (or close to as many) cores as possible.

• Note for Windows 10 users: it is **strongly** recommended to avoid using the .Rprofile file to set mc.cores (using the cores argument or setting mc.cores interactively or in a script is fine).

For is.psis(), an object to check.

Value

Х

The psis() methods return an object of class "psis", which is a named list with the following components:

log_weights Vector or matrix of smoothed (and truncated) but *unnormalized* log weights. To get normalized weights use the weights() method provided for objects of class "psis".

diagnostics A named list containing two vectors:

- pareto_k: Estimates of the shape parameter k of the generalized Pareto distribution. See the pareto-k-diagnostic page for details.
- n_eff: PSIS effective sample size estimates.

Objects of class "psis" also have the following attributes:

norm_const_log Vector of precomputed values of colLogSumExps(log_weights) that are used internally by the weights method to normalize the log weights.

tail_len Vector of tail lengths used for fitting the generalized Pareto distribution.

r_eff If specified, the user's r_eff argument.

dims Integer vector of length 2 containing S (posterior sample size) and N (number of observations). method Method used for importance sampling, here psis.

Methods (by class)

- psis(array): An I by C by N array, where I is the number of MCMC iterations per chain, C is the number of chains, and N is the number of data points.
- psis(matrix): An S by N matrix, where S is the size of the posterior sample (with all chains merged) and N is the number of data points.
- psis(default): A vector of length S (posterior sample size).

- loo() for approximate LOO-CV using PSIS.
- pareto-k-diagnostic for PSIS diagnostics.
- The **loo** package vignettes for demonstrations.
- The FAQ page on the **loo** website for answers to frequently asked questions.

Examples

```
log_ratios <- -1 * example_loglik_array()
r_eff <- relative_eff(exp(-log_ratios))
psis_result <- psis(log_ratios, r_eff = r_eff)
str(psis_result)
plot(psis_result)

# extract smoothed weights
lw <- weights(psis_result) # default args are log=TRUE, normalize=TRUE
ulw <- weights(psis_result, normalize=FALSE) # unnormalized log-weights
w <- weights(psis_result, log=FALSE) # normalized weights (not log-weights)
uw <- weights(psis_result, log=FALSE, normalize = FALSE) # unnormalized weights</pre>
```

psislw

Pareto smoothed importance sampling (deprecated, old version)

Description

As of version 2.0.0 this function is **deprecated**. Please use the psis() function for the new PSIS algorithm.

Usage

```
psislw(
    lw,
    wcp = 0.2,
    wtrunc = 3/4,
    cores = getOption("mc.cores", 1),
    llfun = NULL,
    llargs = NULL,
    ...
)
```

56 relative_eff

Arguments

lw A matrix or vector of log weights. For computing LOO, $lw = -log_lik$, the negative of an S (simulations) by N (data points) pointwise log-likelihood ma-

trix.

wcp The proportion of importance weights to use for the generalized Pareto fit. The

100*wcp\ from which to estimate the parameters of the generalized Pareto dis-

tribution.

wtrunc For truncating very large weights to $S^{\text{-}}$ wtrunc. Set to zero for no truncation.

cores The number of cores to use for parallelization. This defaults to the option

mc.cores which can be set for an entire R session by options(mc.cores = NUMBER), the old option loo.cores is now deprecated but will be given precedence over mc.cores until it is removed. As of version 2.0.0, the default is now 1 core if mc.cores is not set, but we recommend using as many (or

close to as many) cores as possible.

11fun, llargs See loo.function().

.. Ignored when psislw() is called directly. The ... is only used internally when

psislw() is called by the loo() function.

Value

A named list with components lw_smooth (modified log weights) and pareto_k (estimated generalized Pareto shape parameter(s) k).

pareto-k-diagnostic for PSIS diagnostics.

relative_eff Convenience function for computing relative efficiencies

Description

relative_eff() computes the the MCMC effective sample size divided by the total sample size.

relative_eff 57

Usage

```
relative_eff(x, ...)
## Default S3 method:
relative_eff(x, chain_id, ...)
## S3 method for class 'matrix'
relative_eff(x, chain_id, ..., cores = getOption("mc.cores", 1))
## S3 method for class 'array'
relative_eff(x, ..., cores = getOption("mc.cores", 1))
## S3 method for class '`function`'
relative_eff(
  х,
  chain_id,
 cores = getOption("mc.cores", 1),
 data = NULL,
  draws = NULL
)
## S3 method for class 'importance_sampling'
relative_eff(x, ...)
```

Arguments

Х

A vector, matrix, 3-D array, or function. See the **Methods (by class)** section below for details on specifying x, but where "log-likelihood" is mentioned replace it with one of the following depending on the use case:

- For use with the loo() function, the values in x (or generated by x, if a function) should be **likelihood** values (i.e., exp(log_lik)), not on the log scale.
- For generic use with psis(), the values in x should be the reciprocal of the importance ratios (i.e., exp(-log_ratios)).

chain_id

A vector of length NROW(x) containing MCMC chain indexes for each each row of x (if a matrix) or each value in x (if a vector). No chain_id is needed if x is a 3-D array. If there are C chains then valid chain indexes are values in 1:C.

cores

The number of cores to use for parallelization.

data, draws, ... Same as for the loo() function method.

Value

A vector of relative effective sample sizes.

Methods (by class)

• relative_eff(default): A vector of length S (posterior sample size).

58 sis

• relative_eff(matrix): An S by N matrix, where S is the size of the posterior sample (with all chains merged) and N is the number of data points.

- relative_eff(array): An I by C by N array, where I is the number of MCMC iterations per chain, C is the number of chains, and N is the number of data points.
- relative_eff(`function`): A function f() that takes arguments data_i and draws and returns a vector containing the log-likelihood for a single observation i evaluated at each posterior draw. The function should be written such that, for each observation i in 1:N, evaluating

```
f(data_i = data[i,, drop=FALSE], draws = draws)
```

results in a vector of length S (size of posterior sample). The log-likelihood function can also have additional arguments but data_i and draws are required.

If using the function method then the arguments data and draws must also be specified in the call to loo():

- data: A data frame or matrix containing the data (e.g. observed outcome and predictors)
 needed to compute the pointwise log-likelihood. For each observation i, the ith row of data will be passed to the data_i argument of the log-likelihood function.
- draws: An object containing the posterior draws for any parameters needed to compute
 the pointwise log-likelihood. Unlike data, which is indexed by observation, for each
 observation the entire object draws will be passed to the draws argument of the loglikelihood function.
- The ... can be used if your log-likelihood function takes additional arguments. These arguments are used like the draws argument in that they are recycled for each observation.
- relative_eff(importance_sampling): If x is an object of class "psis", relative_eff() simply returns the r_eff attribute of x.

Examples

```
LLarr <- example_loglik_array()
LLmat <- example_loglik_matrix()
dim(LLarr)
dim(LLmat)

rel_n_eff_1 <- relative_eff(exp(LLarr))
rel_n_eff_2 <- relative_eff(exp(LLmat), chain_id = rep(1:2, each = 500))
all.equal(rel_n_eff_1, rel_n_eff_2)</pre>
```

Standard importance sampling (SIS)

sis

Description

Implementation of standard importance sampling (SIS).

sis 59

Usage

```
sis(log_ratios, ...)
## S3 method for class 'array'
sis(log_ratios, ..., r_eff = NULL, cores = getOption("mc.cores", 1))
## S3 method for class 'matrix'
sis(log_ratios, ..., r_eff = NULL, cores = getOption("mc.cores", 1))
## Default S3 method:
sis(log_ratios, ..., r_eff = NULL)
```

Arguments

log_ratios

An array, matrix, or vector of importance ratios on the log scale (for Importance sampling LOO, these are *negative* log-likelihood values). See the **Methods** (**by class**) section below for a detailed description of how to specify the inputs for each method.

. . .

Arguments passed on to the various methods.

r_eff

Vector of relative effective sample size estimates containing one element per observation. The values provided should be the relative effective sample sizes of $1/\exp(\log_{ratios})$ (i.e., 1/ratios). This is related to the relative efficiency of estimating the normalizing term in self-normalizing importance sampling. See the $relative_{eff}()$ helper function for computing r_{eff} . If using psis with draws of the \log_{ratios} not obtained from MCMC then the warning message thrown when not specifying r_{eff} can be disabled by setting r_{eff} to NA.

cores

The number of cores to use for parallelization. This defaults to the option mc.cores which can be set for an entire R session by options(mc.cores = NUMBER). The old option loo.cores is now deprecated but will be given precedence over mc.cores until loo.cores is removed in a future release. As of version 2.0.0 the default is now 1 core if mc.cores is not set, but we recommend using as many (or close to as many) cores as possible.

 Note for Windows 10 users: it is strongly recommended to avoid using the .Rprofile file to set mc.cores (using the cores argument or setting mc.cores interactively or in a script is fine).

Value

The sis() methods return an object of class "sis", which is a named list with the following components:

log_weights Vector or matrix of smoothed but *unnormalized* log weights. To get normalized weights use the weights() method provided for objects of class sis.

diagnostics A named list containing one vector:

- pareto_k: Not used in sis, all set to 0.
- n_eff: effective sample size estimates.

60 sis

Objects of class "sis" also have the following attributes:

norm_const_log Vector of precomputed values of colLogSumExps(log_weights) that are used internally by the weights method to normalize the log weights.

r_eff If specified, the user's r_eff argument.

tail_len Not used for sis.

dims Integer vector of length 2 containing S (posterior sample size) and N (number of observations). method Method used for importance sampling, here sis.

Methods (by class)

- sis(array): An I by C by N array, where I is the number of MCMC iterations per chain, C is the number of chains, and N is the number of data points.
- sis(matrix): An S by N matrix, where S is the size of the posterior sample (with all chains merged) and N is the number of data points.
- sis(default): A vector of length S (posterior sample size).

- pareto-k-diagnostic for PSIS diagnostics.

Examples

```
log_ratios <- -1 * example_loglik_array()
r_eff <- relative_eff(exp(-log_ratios))
sis_result <- sis(log_ratios, r_eff = r_eff)
str(sis_result)

# extract smoothed weights
lw <- weights(sis_result) # default args are log=TRUE, normalize=TRUE
ulw <- weights(sis_result, normalize=FALSE) # unnormalized log-weights

w <- weights(sis_result, log=FALSE) # normalized weights (not log-weights)
uw <- weights(sis_result, log=FALSE, normalize = FALSE) # unnormalized weights</pre>
```

tis 61

tis

Truncated importance sampling (TIS)

Description

Implementation of truncated (self-normalized) importance sampling (TIS), truncated at S^(1/2) as recommended by Ionides (2008).

Usage

```
tis(log_ratios, ...)
## S3 method for class 'array'
tis(log_ratios, ..., r_eff = 1, cores = getOption("mc.cores", 1))
## S3 method for class 'matrix'
tis(log_ratios, ..., r_eff = 1, cores = getOption("mc.cores", 1))
## Default S3 method:
tis(log_ratios, ..., r_eff = 1)
```

Arguments

log_ratios

An array, matrix, or vector of importance ratios on the log scale (for Importance sampling LOO, these are *negative* log-likelihood values). See the **Methods** (**by class**) section below for a detailed description of how to specify the inputs for each method.

. . .

Arguments passed on to the various methods.

r_eff

Vector of relative effective sample size estimates containing one element per observation. The values provided should be the relative effective sample sizes of $1/\exp(\log_r atios)$ (i.e., 1/ratios). This is related to the relative efficiency of estimating the normalizing term in self-normalizing importance sampling. If r_eff is not provided then the reported (T)IS effective sample sizes and Monte Carlo error estimates can be over-optimistic. If the posterior draws are (near) independent then $r_eff=1$ can be used. r_eff has to be a scalar (same value is used for all observations) or a vector with length equal to the number of observations. The default value is 1. See the $relative_eff()$ helper function for computing r_eff .

cores

The number of cores to use for parallelization. This defaults to the option mc.cores which can be set for an entire R session by options(mc.cores = NUMBER). The old option loo.cores is now deprecated but will be given precedence over mc.cores until loo.cores is removed in a future release. As of version 2.0.0 the default is now 1 core if mc.cores is not set, but we recommend using as many (or close to as many) cores as possible.

• Note for Windows 10 users: it is **strongly** recommended to avoid using the .Rprofile file to set mc.cores (using the cores argument or setting mc.cores interactively or in a script is fine).

62 tis

Value

The tis() methods return an object of class "tis", which is a named list with the following components:

log_weights Vector or matrix of smoothed (and truncated) but *unnormalized* log weights. To get normalized weights use the weights() method provided for objects of class tis.

diagnostics A named list containing one vector:

- pareto_k: Not used in tis, all set to 0.
- n_eff: Effective sample size estimates.

Objects of class "tis" also have the following attributes:

norm_const_log Vector of precomputed values of colLogSumExps(log_weights) that are used internally by the weights()method to normalize the log weights.

r_eff If specified, the user's r_eff argument.

tail_len Not used for tis.

dims Integer vector of length 2 containing S (posterior sample size) and N (number of observations). method Method used for importance sampling, here tis.

Methods (by class)

- tis(array): An I by C by N array, where I is the number of MCMC iterations per chain, C is the number of chains, and N is the number of data points.
- tis(matrix): An S by N matrix, where S is the size of the posterior sample (with all chains merged) and N is the number of data points.
- tis(default): A vector of length S (posterior sample size).

- loo() for approximate LOO-CV.
- pareto-k-diagnostic for PSIS diagnostics.

Examples

```
log_ratios <- -1 * example_loglik_array()
r_eff <- relative_eff(exp(-log_ratios))
tis_result <- tis(log_ratios, r_eff = r_eff)
str(tis_result)

# extract smoothed weights
lw <- weights(tis_result) # default args are log=TRUE, normalize=TRUE</pre>
```

update.psis_loo_ss 63

```
ulw <- weights(tis_result, normalize=FALSE) # unnormalized log-weights
w <- weights(tis_result, log=FALSE) # normalized weights (not log-weights)
uw <- weights(tis_result, log=FALSE, normalize = FALSE) # unnormalized weights</pre>
```

update.psis_loo_ss

Update psis_loo_ss objects

Description

Update psis_loo_ss objects

Usage

```
## S3 method for class 'psis_loo_ss'
update(
   object,
    ...,
   data = NULL,
   draws = NULL,
   observations = NULL,
   r_eff = 1,
   cores = getOption("mc.cores", 1),
   loo_approximation = NULL,
   loo_approximation_draws = NULL,
   llgrad = NULL,
   llhess = NULL
)
```

Arguments

 $object \hspace{1cm} A \hspace{1mm} psis_loo_ss \hspace{1mm} object \hspace{1mm} to \hspace{1mm} update.$

... Currently not used.

data, draws See loo_subsample.function().

observations

The subsample observations to use. The argument can take four (4) types of arguments:

- NULL to use all observations. The algorithm then just uses standard loo() or loo_approximate_posterior().
- A single integer to specify the number of observations to be subsampled.
- A vector of integers to provide the indices used to subset the data. *These observations need to be subsampled with the same scheme as given by the* estimator *argument*.
- A psis_loo_ss object to use the same observations that were used in a previous call to loo_subsample().

64 update.psis_loo_ss

r_eff

Vector of relative effective sample size estimates for the likelihood ($\exp(\log_1 lik)$) of each observation. This is related to the relative efficiency of estimating the normalizing term in self-normalized importance sampling when using posterior draws obtained with MCMC. If MCMC draws are used and r_eff is not provided then the reported PSIS effective sample sizes and Monte Carlo error estimates can be over-optimistic. If the posterior draws are (near) independent then r_eff=1 can be used. r_eff has to be a scalar (same value is used for all observations) or a vector with length equal to the number of observations. The default value is 1. See the relative_eff() helper functions for help computing r_eff.

cores

The number of cores to use for parallelization. This defaults to the option mc.cores which can be set for an entire R session by options(mc.cores = NUMBER). The old option loo.cores is now deprecated but will be given precedence over mc.cores until loo.cores is removed in a future release. As of version 2.0.0 the default is now 1 core if mc.cores is not set, but we recommend using as many (or close to as many) cores as possible.

• Note for Windows 10 users: it is **strongly** recommended to avoid using the .Rprofile file to set mc.cores (using the cores argument or setting mc.cores interactively or in a script is fine).

loo_approximation

What type of approximation of the loo_i's should be used? The default is "plpd" (the log predictive density using the posterior expectation). There are six different methods implemented to approximate loo_i's (see the references for more details):

- "plpd": uses the lpd based on point estimates (i.e., $p(y_i|\hat{\theta})$).
- "lpd": uses the lpds (i,e., $p(y_i|y)$).
- "tis": uses truncated importance sampling to approximate PSIS-LOO.
- "waic": uses waic (i.e., $p(y_i|y) p_{waic}$).
- "waic_grad_marginal": uses waic approximation using first order delta method and posterior marginal variances to approximate p_{waic} (ie. $p(y_i|\hat{\theta})$ -p_waic_grad_marginal). Requires gradient of likelihood function.
- "waic_grad": uses waic approximation using first order delta method and posterior covariance to approximate p_{waic} (ie. $p(y_i|\hat{\theta})$ -p_waic_grad). Requires gradient of likelihood function.
- "waic_hess": uses waic approximation using second order delta method and posterior covariance to approximate p_{waic} (ie. $p(y_i|\hat{\theta})$ -p_waic_grad). Requires gradient and Hessian of likelihood function.

As point estimates of $\hat{\theta}$, the posterior expectations of the parameters are used.

loo_approximation_draws

The number of posterior draws used when integrating over the posterior. This is used if loo_approximation is set to "lpd", "waic", or "tis".

llgrad

The gradient of the log-likelihood. This is only used when loo_approximation is "waic_grad", "waic_grad_marginal", or "waic_hess". The default is NULL.

llhess

The Hessian of the log-likelihood. This is only used with loo_approximation = "waic_hess". The default is NULL.

waic 65

Details

If observations is updated then if a vector of indices or a psis_loo_ss object is supplied the updated object will have exactly the observations indicated by the vector or psis_loo_ss object. If a single integer is supplied, new observations will be sampled to reach the supplied sample size.

Value

A psis_loo_ss object.

waic

Widely applicable information criterion (WAIC)

Description

The waic() methods can be used to compute WAIC from the pointwise log-likelihood. However, we recommend LOO-CV using PSIS (as implemented by the loo() function) because PSIS provides useful diagnostics as well as effective sample size and Monte Carlo estimates.

Usage

```
waic(x, ...)
## S3 method for class 'array'
waic(x, ...)
## S3 method for class 'matrix'
waic(x, ...)
## S3 method for class '`function`'
waic(x, ..., data = NULL, draws = NULL)
is.waic(x)
```

Arguments

```
    A log-likelihood array, matrix, or function. The Methods (by class) section, below, has detailed descriptions of how to specify the inputs for each method.
    draws, data, . . . For the function method only. See the Methods (by class) section below for details on these arguments.
```

Value

```
A named list (of class c("waic", "loo")) with components:
```

```
estimates A matrix with two columns ("Estimate", "SE") and three rows ("elpd_waic", "p_waic", "waic"). This contains point estimates and standard errors of the expected log pointwise predictive density (elpd_waic), the effective number of parameters (p_waic) and the information criterion waic (which is just -2 * elpd_waic, i.e., converted to deviance scale).
```

66 waic

pointwise A matrix with three columns (and number of rows equal to the number of observations) containing the pointwise contributions of each of the above measures (elpd_waic, p_waic, waic).

Methods (by class)

- waic(array): An I by C by N array, where I is the number of MCMC iterations per chain, C is the number of chains, and N is the number of data points.
- waic(matrix): An S by N matrix, where S is the size of the posterior sample (with all chains merged) and N is the number of data points.
- waic(`function`): A function f() that takes arguments data_i and draws and returns a vector containing the log-likelihood for a single observation i evaluated at each posterior draw. The function should be written such that, for each observation i in 1:N, evaluating

```
f(data_i = data[i,, drop=FALSE], draws = draws)
```

results in a vector of length S (size of posterior sample). The log-likelihood function can also have additional arguments but data_i and draws are required.

If using the function method then the arguments data and draws must also be specified in the call to loo():

- data: A data frame or matrix containing the data (e.g. observed outcome and predictors)
 needed to compute the pointwise log-likelihood. For each observation i, the ith row of data will be passed to the data_i argument of the log-likelihood function.
- draws: An object containing the posterior draws for any parameters needed to compute the pointwise log-likelihood. Unlike data, which is indexed by observation, for each observation the entire object draws will be passed to the draws argument of the loglikelihood function.
- The ... can be used if your log-likelihood function takes additional arguments. These arguments are used like the draws argument in that they are recycled for each observation.

### Array and matrix methods
LLarr <- example_loglik_array()
dim(LLarr)

LLmat <- example_loglik_matrix()
dim(LLmat)

waic_arr <- waic(LLarr)
waic_mat <- waic(LLmat)
identical(waic_arr, waic_mat)

## Not run:
log_lik1 <- extract_log_lik(stanfit1)
log_lik2 <- extract_log_lik(stanfit2)
(waic1 <- waic(log_lik1))
(waic2 <- waic(log_lik2))
print(compare(waic1, waic2), digits = 2)

## End(Not run)</pre>
```

```
weights.importance_sampling
```

Extract importance sampling weights

Description

Extract importance sampling weights

Usage

```
## S3 method for class 'importance_sampling'
weights(object, ..., log = TRUE, normalize = TRUE)
```

Arguments

object An object returned by psis(), tis(), or sis().

... Ignored.

log Should the weights be returned on the log scale? Defaults to TRUE.

normalize Should the weights be normalized? Defaults to TRUE.

Value

The weights() method returns an object with the same dimensions as the log_weights component of object. The normalize and log arguments control whether the returned weights are normalized and whether or not to return them on the log scale.

Examples

See the examples at help("psis")
