# Package 'RCLabels' 

January 30, 2024
Title Manipulate Matrix Row and Column Labels with Ease
Version 0.1.10
Date 2024-01-26
Description Functions to assist manipulation of matrix row and column labels for all types of matrix mathematics where row and column labels are to be respected.

arrow_notation Arrow notation

## Description

A description of arrow notation.

## Usage

arrow_notation

## Format

A vector of notational symbols that provides an arrow separator ("a $->\mathrm{b}$ ") between prefix and suffix.

## Examples

arrow_notation

```
bracket_arrow_notation
```

    Bracket arrow notation
    
## Description

A description of bracket arrow notation.

## Usage

bracket_arrow_notation

## Format

A vector of notational symbols that provides bracket arrow ("a [-> b]") notation.

## Examples

```
    bracket_arrow_notation
```

    bracket_notation Bracket notation
    
## Description

A description of bracket notation.

## Usage

bracket_notation

## Format

A vector of notational symbols that provides bracket ("a [b]") notation.

## Examples

bracket_notation

```
dash_notation A description of dash notation.
```

## Description

A description of dash notation.

## Usage

dash_notation

## Format

A vector of notational symbols that provides an dash separator (" $\mathrm{a}-\mathrm{b}$ ") between prefix and suffix.

## Examples

```
dash_notation
```

    first_dot_notation First dot notation
    
## Description

A description of first dot notation. Note that "a.b.c" splits into prefix ("a") and suffix ("b.c").

## Usage

first_dot_notation

## Format

A vector of notational symbols that provides first dot ("a.b") notation.

## Examples

## from_notation From notation

## Description

A description of from notation.

## Usage

from_notation

## Format

A vector of notational symbols that provides from ("a [from b]") notation.

## Examples

from_notation
get_nouns Extract nouns from row and column labels

## Description

Nouns are the first part of a row-column label, "a" in "a [b]". Internally, this function calls get_pref_suff(which = "pref").

## Usage

get_nouns(
labels,
inf_notation = TRUE, notation = RCLabels::notations_list, choose_most_specific = TRUE
)

## Arguments

labels A list or vector of labels from which nouns are to be extracted.
inf_notation A boolean that tells whether to infer notation for $x$. Default is TRUE. See infer_notation() for details.
notation The notation type to be used when extracting nouns. Default is RCLabels: :notations_list, meaning that the notation is inferred using infer_notation().
choose_most_specific
A boolean that tells whether to choose the most specific notation from notation when inferring notation. Default is TRUE.

## Value

A list of nouns from row and column labels.

## Examples

```
get_nouns("a [b]", notation = bracket_notation)
# Also works with vectors and lists.
get_nouns(c("a [b]", "c [d]"))
get_nouns(list("a [b]", "c [d]"))
```

get_objects Extract objects of prepositional phrases in row and column labels

## Description

This function extracts the objects of prepositional phrases from row and column labels. The format of the output is a list of named items, one name for each preposition encountered in labels. Objects are NA if there is no prepositional phrase starting with that preposition.

## Usage

get_objects(
labels,
inf_notation = TRUE,
notation = RCLabels: :notations_list,
choose_most_specific = FALSE,
prepositions = RCLabels::prepositions_list
)

## Arguments

labels The row and column labels from which prepositional phrases are to be extracted.
inf_notation A boolean that tells whether to infer notation for $x$. Default is TRUE. See infer_notation() for details.
notation The notation type to be used when extracting prepositions. Default is RCLabels: :notations_list, meaning that the notation is inferred using infer_notation().
choose_most_specific
A boolean that tells whether to choose the most specific notation from notation when inferring notation. Default is FALSE so that a less specific notation can be inferred. In combination with RCLabels: :notations_list, the default value of FALSE means that RCLabels: : bracket_notation will be selected instead of anything more specific, such as RCLabels: :from_notation.
prepositions A vector of strings to be treated as prepositions. Note that a space is appended to each word internally, so, e.g., "to" becomes "to ". Default is RCLabels: :prepositions_list.

## Value

A list of objects of prepositional phrases, with names being prepositions, and values being objects.

## Examples

```
get_objects(c("a [of b into c]", "d [of Coal from e -> f]"))
```

```
get_piece Get a piece of a label
```

## Description

This is a wrapper function for get_pref_suff(), get_nouns(), and get_objects(). It returns a piece of a row or column label.

## Usage

```
get_piece(
    labels,
    piece = "all",
    inf_notation = TRUE,
    notation = RCLabels::notations_list,
    choose_most_specific = FALSE,
    prepositions = RCLabels::prepositions_list
)
```

## Arguments

labels The row and column labels from which prepositional phrases are to be extracted.
piece The name of the item to return.
inf_notation A boolean that tells whether to infer notation for $x$. Default is TRUE. See infer_notation() for details.
notation The notation type to be used when extracting prepositions. Default is RCLabels: :notations_list, meaning that the notation is inferred using infer_notation().
choose_most_specific
A boolean that tells whether to choose the most specific notation from notation when inferring notation. Default is FALSE so that a less specific notation can be inferred. In combination with RCLabels: :notations_list, the default value of FALSE means that RCLabels: : bracket_notation will be selected instead of anything more specific, such as RCLabels: :from_notation.
prepositions A vector of strings to be treated as prepositions. Note that a space is appended to each word internally, so, e.g., "to" becomes "to ". Default is RCLabels: :prepositions_list.

## Details

piece is typically one of

- "all" (which returns labels directly),
- "pref" (for the prefixes),
- "suff" (for the suffixes),
- "noun" (returns the noun),
- "pps" (prepositional phrases, returns prepositional phrases in full),
- "prepositions" (returns a list of prepositions),
- "objects" (returns a list of objects with prepositions as names), or
- a preposition in prepositions (as a string), which will return the object of that preposition named by the preposition itself.
piece must be a character vector of length 1 . If a piece is missing in a label, "" (empty string) is returned.

If specifying more than one notation, be sure the notations are in a list. notation = c (RCLabels: :bracket_notation, RCLabels::arrow_notation) is unlikely to produce the desired result, because the notations are concatenated together to form a long string vector. Rather say notation = list(RCLabels: :bracket_notation, RCLabels::arrow_notation).

## Value

A piece of labels.

## Examples

```
labs <- c("a [from b in c]", "d [of e in f]", "Export [of Coal from USA to MEX]")
get_piece(labs, "pref")
get_piece(labs, "suff")
get_piece(labs, piece = "noun")
get_piece(labs, piece = "pps")
get_piece(labs, piece = "prepositions")
get_piece(labs, piece = "objects")
get_piece(labs, piece = "from")
get_piece(labs, piece = "in")
get_piece(labs, piece = "of")
get_piece(labs, piece = "to")
```

get_pps Extract prepositional phrases of row and column labels

## Description

This function extracts prepositional phrases from suffixes of row and column labels of the form "a [preposition b]", where "preposition b" is the prepositional phrase.

```
Usage
    get_pps(
        labels,
        inf_notation = TRUE,
        notation = RCLabels::notations_list,
        choose_most_specific = FALSE,
        prepositions = RCLabels::prepositions_list
    )
```

## Arguments

labels A list or vector of labels from which prepositional phrases are to be extracted.
inf_notation A boolean that tells whether to infer notation for $x$. Default is TRUE. See infer_notation() for details.
notation The notation type to be used when extracting prepositional phrases. Default is RCLabels: :notations_list, meaning that the notation is inferred using infer_notation().
choose_most_specific
A boolean that tells whether to choose the most specific notation from notation when inferring notation. Default is FALSE so that a less specific notation can be inferred. In combination with RCLabels: :notations_list, the default value of FALSE means that RCLabels: : bracket_notation will be selected instead of anything more specific, such as RCLabels: :from_notation.
prepositions A list of prepositions for which to search. Default is RCLabels: :prepositions_list.

## Value

All prepositional phrases in a suffix.

## Examples

```
get_pps(c("a [in b]", "c [of d]"))
get_pps(c("a [of b in c]", "d [-> e of f]"))
```

get_prepositions Extract prepositions from row and column labels

## Description

This function extracts prepositions from a list of row and column labels. The list has outer structure of the number of labels and an inner structure of each prepositional phrase in the specific label.

## Usage

```
    get_prepositions(
        labels,
        inf_notation = TRUE,
        notation = RCLabels::notations_list,
        choose_most_specific = FALSE,
        prepositions = RCLabels::prepositions_list
    )
```

## Arguments

| labels | The row and column labels from which prepositional phrases are to be extracted. |
| :--- | :--- |
| inf_notation | A boolean that tells whether to infer notation for $x$. Default is TRUE. See infer_notation() <br> for details. |
| notation | The notation type to be used when extracting prepositions. Default is RCLabels: :notations_list, <br> meaning that the notation is inferred using infer_notation(). |
| choose_most_specific |  |
| A boolean that tells whether to choose the most specific notation from notation |  |
| when inferring notation. Default is FALSE so that a less specific notation can be |  |
| inferred. In combination with RCLabels : : notations_list, the default value |  |
| of FALSE means that RCLabels: :bracket_notation will be selected instead of |  |
| anything more specific, such as RCLabels: :from_notation. |  |

## Value

A list of prepositions.

## Examples

get_prepositions(c("a [of b into c]", "d [-> e of f]"))
infer_notation Infer the notation(s) for a row or column label

## Description

It is convenient to know which notation is applicable to row or column labels. This function infers which notations are appropriate for x .

## Usage

```
infer_notation(
    x ,
    inf_notation = TRUE,
    notations = RCLabels::notations_list,
    allow_multiple = FALSE,
    retain_names = FALSE,
    choose_most_specific = TRUE,
    must_succeed \(=\) TRUE
)
```

## Arguments

$x \quad$ A row or column label (or vector of labels).
inf_notation A boolean that tells whether to infer notation for $x$. Default is TRUE.
notations A list of notations from which matches will be inferred. This function might not work as expected if notation is not a list. If notation is not a list, notations is returned in full. Default is RCLabels: :notations_list.
allow_multiple A boolean that tells whether multiple notation matches are allowed. If FALSE (the default), multiple matches give an error.
retain_names A boolean that tells whether to retain names from notations on the outgoing matches. Default is FALSE. If TRUE, the return value is always a named list. If only one of notations is returned (for example, because choose_most_specific $=$ TRUE), names are never supplied.
choose_most_specific
A boolean that indicates whether the most-specific notation will be returned when more than one of notations matches $x$ and allow_multiple $=$ FALSE. When FALSE, the first matching notation in notations is returned when allow_multiple = FALSE. Default is TRUE. See details.
must_succeed A boolean that if TRUE (the default), causes an error to be thrown if a matching notation is not found for any label in $x$. When FALSE, an unsuccessful notation inference will return NULL.

## Details

This function is vectorized. Thus, $x$ can be a vector, in which case the output is a list of notations. notations is treated as a store from which matches for each label in $x$ can be determined. notations should be a named list of notations. When retain_names = TRUE, the names on notations will be retained, and the return value is always a list.
By default (allow_multiple = FALSE), a single notation object is returned for each item in $x$ if only one notation in notations is appropriate for $x$. If allow_multiple = FALSE (the default) and more than one notation is applicable to $x$, an error is thrown. Multiple matches can be returned when allow_multiple = TRUE.
If multiple notations are matched, the return value is a list.
When choose_most_specific = TRUE (the default), the most specific notation in notations is returned. "Most specific" is defined as the matching notation whose sum of characters in the
pref_start, pref_end, suff_start and suff_end elements is greatest. If choose_most_specific $=$ TRUE and two matching notations in notations have the same number of characters, only the first match is returned. When choose_most_specific = TRUE, the value of allow_multiple no longer matters. allow_multiple = FALSE is implied and at most one of the notations will be returned.
When inf_notation = FALSE (default is TRUE), notations are returned unmodified, essentially disabling this function. Although calling with inf_notation = FALSE seems daft, this behavior enables cleaner code elsewhere.

## Value

A single notation object (if x is a single row or column label) or a list of notation objects (if x is a vector or a list). If no notations match $x$, NULL is returned, either alone or in a list.

## Examples

```
# Does not match any notations in RCLabels::notations_list
# and throws an error, because the default value for `must_succeed`
# is `TRUE`.
## Not run:
infer_notation("abc")
## End(Not run)
# This returns `NULL`, because `must_succeed = FALSE`.
infer_notation("abc", must_succeed = FALSE)
# This succeeds, because the label is in the form of a
# notation in `RCLabels::notation_list`,
# the default value of the `notation` argument.
infer_notation("a -> b")
# Names of the notations can be retained, in which case
# the return value is always a list.
infer_notation("a -> b", retain_names = TRUE)
# This function is vectorized.
# The list of labels matches
# all known notations in `RCLabels::notations_list`.
infer_notation(c("a -> b", "a (b)", "a [b]", "a [from b]", "a [of b]",
    "a [to b]", "a [in b]", "a [-> b]", "a.b"),
    retain_names = TRUE)
# By default, the most specific notation is returned.
# But when two or more matches are present,
# multiple notations can be returned, too.
infer_notation("a [from b]",
    allow_multiple = TRUE, retain_names = TRUE,
    choose_most_specific = FALSE)
infer_notation(c("a [from b]", "c [to d]"),
    allow_multiple = TRUE, retain_names = TRUE,
    choose_most_specific = FALSE)
# As shown above, "a \[from b\]" matches 2 notations:
# `RCLabels::bracket_notation` and `RCLabels::from_notation`.
# The default value for the notation argument is
# RCLabels::notations_list,
# which includes `RCLabels::bracket_notation`
# and `RCLabels::from_notation` in that order.
```

```
    # Thus, there is some flexibility to how this function works
    # if the value of the `notation` argument is a list of notations
    # ordered from least specific to most specific,
    # as `RCLabels::notations_list` is ordered.
    # To review, the next call returns both `RCLabels::bracket_notation` and
    # `RCLabels::from_notation`, because `allow_multiple = TRUE` and
    # `choose_most_specific = FALSE`, neither of which are default.
    infer_notation("a [from b]",
    allow_multiple = TRUE,
    choose_most_specific = FALSE,
    retain_names = TRUE)
    # The next call returns `RCLabels::from_notation`, because
    # the most specific notation is requested, and
    # `RCLabels::from_notation` has more characters in its specification than
    # `RCLabels::bracket_notation`.
    infer_notation("a [from b]",
    choose_most_specific = TRUE,
    retain_names = TRUE)
    # The next call returns the `RCLabels::bracket_notation`, because
    # `choose_most_specific = FALSE`, and the first matching
    # notation in `RCLabels::notations_list` is `RCLabels::bracket_notation`.
    infer_notation("a [from b]",
        choose_most_specific = FALSE,
        retain_names = TRUE)
```

    infer_notation_for_one_label
    Infer the notation from one row or column label
    
## Description

This is a non-public helper function for vectorized infer_notation().

## Usage

```
infer_notation_for_one_label(
    x,
    inf_notation = TRUE,
    notations = RCLabels::notations_list,
    allow_multiple = FALSE,
    retain_names = FALSE,
    choose_most_specific = TRUE,
    must_succeed = TRUE
)
```

## Arguments

## $x$

A single row or column label.
inf_notation A boolean that tells whether to infer notation for x .

#### Abstract

notations A list of notations from which matches will be inferred This function might not work as expected if notation is not a list. If notation is not a list, notations is returned in full. Default is RCLabels: :notations_list. allow_multiple A boolean that tells whether multiple notation matches are allowed. If FALSE (the default), multiple matches give an error. retain_names A boolean that tells whether to retain names on the outgoing matches. Default is FALSE. If TRUE, the return value is a named list. If only one of notations is returned, names are never supplied. ```choose_most_specific```

A boolean that indicates if the most-specific notation will be returned when more than one of notations matches $x$. Default is TRUE. must_succeed A boolean that if TRUE (the default), causes an error to be thrown if a matching notation is not found for any label in $x$. When FALSE, an unsuccessful label inference will return NULL.

## Value

A single matching notation object (if allow_multiple = FALSE, the default) or possibly multiple matching notation objects (if allow_multiple $=$ TRUE). If no notations match $x$, NULL.

```
in_notation In notation
```

## Description

A description of in notation.

## Usage

in_notation

## Format

A vector of notational symbols that provides to ("a [in b]") notation.

## Examples

in_notation

```
make_list Make a list of items in x, regardless of x's type
```

## Description

Repeats x as necessary to make n of them. Does not try to simplify x .

## Usage

make_list(x, $n$, lenx $=$ ifelse(is.vector( $x$ ), length( $x$ ), 1))

## Arguments

x
The object to be duplicated.
n
The number of times to be duplicated.
lenx $\quad$ The length of item $x$. Be default, lenx is taken to be length(x),

## Details

If $x$ is itself a vector or list, you may want to override the default value for lenx. For example, if $x$ is a list that should be duplicated several times, set lenx $=1$.

## Value

A list of $x$ duplicated $n$ times

## Examples

```
m <- matrix(c(1:6), nrow=3, dimnames = list(c("r1", "r2", "r3"), c("c2", "c1")))
make_list(m, n = 1)
make_list(m, n = 2)
make_list(m, n = 5)
make_list(list(c(1,2), c(1,2)), n = 4)
m <- matrix(1:4, nrow = 2)
l <- list(m, m+100)
make_list(l, n = 4)
make_list(l, n = 1) # Warning because l is trimmed.
make_list(l, n = 5) # Warning because length(l) (i.e., 2) not evenly divisible by 5
make_list(list(c("r10", "r11"), c("c10", "c11")), n = 2) # Confused by x being a list
make_list(list(c("r10", "r11"), c("c10", "c11")), n = 2, lenx = 1) # Fix by setting lenx = 1
```

```
make_or_pattern Create "or" regex patterns
```

## Description

This function makes "or" regex patterns from vectors or lists of strings. This function can be used with the matsbyname::select_rows_byname() and matsbyname::select_cols_byname functions. make_or_pattern() correctly escapes special characters in strings, such as ( and ), as needed. Thus, it is highly recommended that make_or_pattern be used when constructing patterns for row and column selections with matsbyname: :select_rows_byname() and matsbyname: :select_cols_byname().

```
Usage
    make_or_pattern(
        strings,
        pattern_type = c("exact", "leading", "trailing", "anywhere", "literal")
    )
```

## Arguments

strings A vector of row and column names.
pattern_type One of "exact", "leading", "trailing", "anywhere", or "literal". Default is "exact".

## Details

pattern_type controls the type of pattern created:

- exact produces a regex pattern that selects row or column names by exact match.
- leading produces a regex pattern that selects row or column names if the item in strings matches the beginnings of row or column names.
- trailing produces a regex pattern that selects row or column names if the item in strings matches the ends of row or column names.
- anywhere produces a regex pattern that selects row or column names if the item in strings matches any substring of row or column names.
- literal returns strings unmodified, and it is up to the caller to formulate a correct regex.

## Value

An "or" regex pattern suitable for selecting row and column names. Amenable for use with matsbyname : :select_rows_byn or matsbyname: :select_cols_byname.

## Examples

```
make_or_pattern(strings = c("a", "b"), pattern_type = "exact")
make_or_pattern(strings = c("a", "b"), pattern_type = "leading")
make_or_pattern(strings = c("a", "b"), pattern_type = "trailing")
make_or_pattern(strings = c("a", "b"), pattern_type = "anywhere")
make_or_pattern(strings = c("a", "b"), pattern_type = "literal")
```

```
modify_label_pieces Modify pieces of row and column labels
```

## Description

Typical pieces include "noun" or a preposition, such as "in" or "from". See RCLabels: :prepositions for additional examples. This argument may be a single string or a character vector.

## Usage

```
    modify_label_pieces(
        labels,
        piece,
        mod_map,
        prepositions = RCLabels::prepositions_list,
        inf_notation = TRUE,
        notation = RCLabels::bracket_notation,
        choose_most_specific = FALSE
    )
```

## Arguments

labels A vector of row or column labels in which pieces will be modified.
piece $\quad$ The piece (or pieces) of the row or column label that will be modified.
mod_map A modification map. See details.
prepositions A list of prepositions, used to detect prepositional phrases. Default is RCLabels: :prepositions_list.
inf_notation A boolean that tells whether to infer notation for $x$. Default is TRUE. See infer_notation() for details.
notation The notation type to be used when extracting prepositions. Default is RCLabels: :notations_list, meaning that the notation is inferred using infer_notation().
choose_most_specific
A boolean that tells whether the most specific notation is selected when more than one notation match. Default is FALSE.

## Details

This function modifies pieces of row and column labels according to label_map that defines "one or many to one" relationships. This function is useful for aggregations. For example, replacing nouns can be done by modify_label_pieces(labels, piece = "noun", label_map = list(new_noun = c("a", "b", "c")). The string "new_noun" will replace any of "a", "b", or "c" when they appear as nouns in a row or column label. See examples for details.
The mod_map argument should consist of a named list of character vectors in which names indicate strings to be inserted and values indicate values that should be replaced. The sense is new =old or new = olds, where "new" is the new name (the replacement) and "old"/"olds" is/are a string/vector of strings, any one of which will be replaced by "new".

Note piece can be "pref"/"suff" or "noun"/"prepositions" If any piece is "pref" or "suff", all pieces are assumed to be a prefix or a suffix. If non of the pieces are "pref" or "suff", all pieces are assumed to be nouns or prepositions, such as "in" or "from". See RCLabels:: prepositions for additional examples. This argument may be a single string or a character vector.

## Value

labels with replacements according to piece and mod_map.

## Examples

```
    # Simple case
    modify_label_pieces("a [of b in c]",
        piece = "noun",
        mod_map = list(new_noun = c("a", "b")))
    # Works with a vector or list of labels
modify_label_pieces(c("a [of b in c]", "d [-> e in f]"),
    piece = "noun",
    mod_map = list(new_noun = c("d", "e")))
# Works with multiple items in the mod_map
modify_label_pieces(c("a [of b in c]", "d [-> e in f]"),
    piece = "noun",
    mod_map = list(new_noun1 = c("a", "b", "c"),
    new_noun2 = c("d", "e", "f")))
# Works with multiple pieces to be modified
modify_label_pieces(c("a [of b in c]", "d [-> e in f]"),
    piece = c("noun", "in"),
    mod_map = list(new_noun = c("a", "b", "c"),
    new_in = c("c", "f")))
```

    modify_nouns Modify nouns in labels
    
## Description

This function modifies the nouns of row and column labels. The length of new_nouns must be the same as the length of labels.

## Usage

```
modify_nouns(
    labels,
    new_nouns,
    inf_notation = TRUE,
    notation = RCLabels::notations_list,
    choose_most_specific = FALSE
)
```

## Arguments

labels The row and column labels in which the nouns will be modified.
new_nouns The new nouns to be set in labels. Must be same length as labels.
inf_notation A boolean that tells whether to infer notation for labels. Default is TRUE. See infer_notation() for details.
notation The notation type to be used when extracting prepositions. Default is RCLabels: :notations_list, meaning that the notation is inferred using infer_notation().
choose_most_specific
A boolean that tells whether to choose the most specific notation from notation when inferring notation. Default is FALSE so that a less specific notation can be inferred. In combination with RCLabels: :notations_list, the default value of FALSE means that RCLabels: : bracket_notation will be selected instead of anything more specific, such as RCLabels: :from_notation.

## Value

A character vector of same length as labels with nouns modified to be new_nouns.

## Examples

```
labels <- c("a [of b in c]", "d [of e in USA]")
modify_nouns(labels, c("a_plus", "g"))
```

```
notations_list Notations list
```

## Description

A list of all bundled notations. This list is organized by least specific to most specific, thereby enabling some unique behaviors in infer_notation(). See the examples for infer_notation().

## Usage

notations_list

## Format

A list of bundled notations.

## Examples

```
notations_list
```

of_notation Of notation

## Description

A description of of notation.

## Usage

of_notation

## Format

A vector of notational symbols that provides of ("a [of b]") notation.

## Examples

of_notation
paren_notation Parenthetical notation

## Description

A description of parenthetical notation.

## Usage

paren_notation

## Format

A vector of notational symbols that provides a parenthetical ("a (b)") notation.

## Examples

paren_notation

```
paste_noun_pp Recombine row and column labels
```

## Description

This function recombines (unsplits) row or column labels that have been separated by split_noun_pp().

## Usage

```
paste_noun_pp(
        splt_labels,
        notation = RCLabels::bracket_notation,
        squish = TRUE
    )
```

## Arguments

| splt_labels | A vector of split row or column labels, probably created by split_noun_pp(). |
| :--- | :--- |
| notation | The notation object that describes the labels. Default is RCLabels: :bracket_notation. |
| squish | A boolean that tells whether to remove extra spaces in the output of paste_*() <br> functions. Default is TRUE. |

## Value

Recombined row and column labels.

## Examples

```
labs <- c("a [of b in c]", "d [from Coal mines in USA]")
labs
split <- split_noun_pp(labs)
split
paste_noun_pp(split)
# Also works in a data frame
df <- tibble::tibble(labels = c("a [in b]", "c [of d into USA]",
                    "e [of f in g]", "h [-> i in j]"))
recombined <- df %>%
        dplyr::mutate(
            splits = split_noun_pp(labels),
        recombined = paste_noun_pp(splits)
    )
all(recombined$labels == recombined$recombined)
```

## prepositions Prepositions

## Description

This constant is deprecated. Please use prepositiions_list instead.

## Usage

prepositions

## Format

A vector of prepositions used in row and column labels.

```
prepositions_list Prepositions
```

## Description

Prepositions used in row and column labels.

## Usage

prepositions_list

## Format

A vector of prepositions used in row and column labels.

## Examples

```
prepositions_list
```

## Description

match_by_pattern() tells whether row or column labels match a regular expression. Internally, grepl() decides whether a match occurs. replace_by_pattern() replaces portions of row of column labels when a regular expression is matched. Internally, gsub() performs the replacements.

## Usage

match_by_pattern(
labels,
regex_pattern, pieces = "all", prepositions = RCLabels: :prepositions_list, notation = RCLabels::bracket_notation,
)
replace_by_pattern(
labels,
regex_pattern, replacement, pieces = "all", prepositions = RCLabels::prepositions_list, notation = RCLabels::bracket_notation,
)

## Arguments

labels The row and column labels to be modified.
regex_pattern The regular expression pattern to determine matches and replacements. Consider using Hmisc: :escapeRegex() to escape regex_pattern before calling this function.
pieces The pieces of row or column labels to be checked for matches or replacements. See details.
prepositions A vector of strings that count as prepositions. Default is RCLabels: :prepositions_list. Used to detect prepositional phrases if pieces are to be interpreted as prepositions.
notation The notation used in labels. Default is RCLabels: :bracket_notation.
$\ldots \quad$ Other arguments passed to grepl() or gsub(), such as ignore.case, perl, fixed, or useBytes. See examples.
replacement For replace_by_pattern(), the string that replaces all matches to regex_pattern.

## Details

By default (pieces = "all"), complete labels (as strings) are checked for matches and replacements. If pieces == "pref" or pieces == "suff", only the prefix or the suffix is checked for matches and replacements. Alternatively, pieces = "noun" or pieces = <<preposition>> indicate that only specific pieces of labels are to be checked for matches and replacements. When pieces $=$ <<preposition>>, only the object of <<preposition>> is checked for matches and replacement.
pieces can be a vector, indicating multiple pieces to be checked for matches and replacements. But if any of the pieces are "all", all pieces are checked and replaced. If pieces is "pref" or "suff", only one can be specified.

## Value

A logical vector of same length as labels, where TRUE indicates a match was found and FALSE indicates otherwise.

## Examples

```
labels <- c("Production [of b in c]", "d [of Coal in f]", "g [of h in USA]")
# With default `pieces` argument, matching is done for whole labels.
match_by_pattern(labels, regex_pattern = "Production")
match_by_pattern(labels, regex_pattern = "Coal")
match_by_pattern(labels, regex_pattern = "USA")
# Check beginnings of labels
match_by_pattern(labels, regex_pattern = "^Production")
# Check at ends of labels: no match.
match_by_pattern(labels, regex_pattern = "Production$")
# Can match on nouns or prepositions.
match_by_pattern(labels, regex_pattern = "Production", pieces = "noun")
# Gives FALSE, because "Production" is a noun.
match_by_pattern(labels, regex_pattern = "Production", pieces = "in")
```

remove_label_pieces Remove a prepositional phrase in a row or column label

## Description

This function removes pieces from row and column labels.

## Usage

remove_label_pieces(
labels,
pieces_to_remove,
prepositions = RCLabels: prepositions_list,
inf_notation = TRUE,
notation = RCLabels::notations_list,
choose_most_specific = FALSE
)

## Arguments

$$
\begin{aligned}
& \text { labels } \begin{array}{l}
\text { The row and column labels from which prepositional phrases will be removed. } \\
\text { pieces_to_remove } \\
\text { The names of pieces of the label to be removed, typically "noun" or a preposition } \\
\text { such as "of" or "in" See RCLabels: :prepositions_list for a list of known } \\
\text { prepositions. }
\end{array} \\
& \text { prepositions } \quad \begin{array}{l}
\text { A list of prepositions, used to detect prepositional phrases. Default is RCLabels: :prepositions_list. } \\
\text { inf_notation } \\
\text { A boolean that tells whether to infer notation for } x \text {. Default is TRUE. See infer_notation() } \\
\text { for details. }
\end{array} \\
& \text { notation } \quad \begin{array}{l}
\text { The notation type to be used when extracting prepositions. Default is RCLabels: :notations_list, } \\
\text { meaning that the notation is inferred using infer_notation(). }
\end{array} \\
& \text { choose_most_specific } \\
& \text { A boolean that tells whether the most specific notation is selected when more } \\
& \text { than one notation match. Default is FALSE. }
\end{aligned}
$$

## Value

labels with pieces removed.

## Examples

```
labs <- c("a [of b in c]", "d [-> e in f]")
remove_label_pieces(labs, pieces_to_remove = "of")
remove_label_pieces(labs, pieces_to_remove = c("of", "->"))
remove_label_pieces(labs, pieces_to_remove = c("in", "into"))
remove_label_pieces(labs, pieces_to_remove = c("of", "in"))
```

```
row-col-notation
```

## Description

It is often convenient to represent matrix row and column names with notation that includes a prefix and a suffix, with corresponding separators or start-end string sequences. There are several functions to generate specialized versions or otherwise manipulate row and column names on their own or as row or column names.

- flip_pref_suff() Switches the location of prefix and suffix, such that the prefix becomes the suffix, and the suffix becomes the prefix. E.g., "a-> b" becomes " $\mathrm{b}-\mathrm{>} \mathrm{a}$ " or "a [b]" becomes "b [a]".
- get_pref_suff() Selects only prefix or suffix, discarding notational elements and the rejected part. Internally, this function calls split_pref_suff() and selects only the desired portion.
- notation_vec() Builds a vector of notation symbols in a standard format. By default, it builds a list of notation symbols that provides an arrow separator (" $->$ ") between prefix and suffix.
- paste_pref_suff() paste0's prefixes and suffixes, the inverse of split_pref_suff(). Always returns a character vector.
- preposition_notation() Builds a list of notation symbols that provides (by default) square brackets around the suffix with a preposition ("prefix [preposition suffix]").
- split_pref_suff() Splits prefixes from suffixes, returning each in a list with names pref and suff. If no prefix or suffix delimiters are found, $x$ is returned in the pref item, unmodified, and the suff item is returned as "" (an empty string). If there is no prefix, and empty string is returned for the pref item. If there is no suffix, and empty string is returned for the suff item.
- switch_notation() Switches from one type of notation to another based on the from and to arguments. Optionally, prefix and suffix can be flipped.

Parts of a notation vector are "pref_start", "pref_end", "suff_start", and "suff_end". None of the strings in a notation vector are considered part of the prefix or suffix. E.g., "a -> b" in arrow notation means that "a" is the prefix and " b " is the suffix. If sep only is specified for notation_vec() (default is " -> "), pref_start, pref_end, suff_start, and suff_end are set appropriately.
For functions where the notation argument is used to identify portions of the row or column label (such as split_pref_suff(), get_pref_suff(), and the from argument to switch_notation()), (Note: flip_pref_suff() cannot infer notation, because it switches prefix and suffix in a known, single notation.) if notation is a list, it is treated as a store from which the most appropriate notation is inferred by infer_notation(choose_most_specific = TRUE). Because default is RCLabels: :notations_list, notation is inferred by default. The argument choose_most_specific tells what to do when two notations match a label: if TRUE (the default), the notation with most characters is selected. If FALSE, the first matching notation in notation will be selected. See details at infer_notation().
If specifying more than one notation, be sure the notations are in a list. notation = $c$ (RCLabels: :bracket_notation, RCLabels: :arrow_notation) is unlikely to produce the desired result, because the notations are concatenated together to form a long string vector. Rather say notation = list(RCLabels: :bracket_notation, RCLabels::arrow_notation).

For functions that construct labels (such as paste_pref_suff()), notation can be a list of notations over which the paste tasks is mapped. If notation is a list, it must have as many items as there are prefix/suffix pairs to be pasted.
If either pref or suff are a zero-length character vector (essentially an empty character vector such as obtained from character()) input to paste_pref_suff(), an error is thrown. Instead, use an empty character string (such as obtained from "").

```
Usage
notation_vec(
    sep = " -> ",
    pref_start = "",
    pref_end = "",
    suff_start = "",
    suff_end = ""
)
```

preposition_notation(preposition, suff_start = " [", suff_end = "]")

```
split_pref_suff(
    x,
    transpose = FALSE,
    inf_notation = TRUE,
    notation = RCLabels::notations_list,
    choose_most_specific = TRUE
)
paste_pref_suff(
    ps = list(pref = pref, suff = suff),
    pref = NULL,
    suff = NULL,
    notation = RCLabels::arrow_notation,
    squish = TRUE
)
flip_pref_suff(
    x,
    notation = RCLabels::notations_list,
    inf_notation = TRUE,
    choose_most_specific = TRUE
)
get_pref_suff(
    x,
    which = c("pref", "suff"),
    inf_notation = TRUE,
    notation = RCLabels::notations_list,
    choose_most_specific = TRUE
)
switch_notation(
        x,
        from = RCLabels::notations_list,
    to,
    flip = FALSE,
    inf_notation = TRUE
)
```

## Arguments

sep A string separator between prefix and suffix. Default is " -> ".
pref_start A string indicating the start of a prefix. Default is NULL.
pref_end A string indicating the end of a prefix. Default is the value of sep.
suff_start A string indicating the start of a suffix. Default is the value of sep.
suff_end A string indicating the end of a suffix. Default is NULL.

| preposition | A string used to indicate position for energy flows, typically "from" or "to" in different notations. |
| :---: | :---: |
| x | A string or vector of strings to be operated upon. |
| transpose | A boolean that tells whether to purr:: transpose() the result. Set transpose = TRUE when using split_pref_suff() in a dplyr: :mutate() call in the context of a data frame. Default is FALSE. |
| inf_notation | A boolean that tells whether to infer notation for $x$. Default is TRUE. See infer_notation() for details. |
| notation | A notation vector generated by one of the *_notation() functions, such as notation_vec(), arrow_notation, or bracket_notation. |
| choose_most_specific |  |
|  | A boolean that tells whether to choose the most specific notation from the notation argument when the notation argument is a list. |
| ps | A list of prefixes and suffixes in which each item of the list is itself a list with two items named pref and suff. |
| pref | A string or list of strings that are prefixes. Default is NULL. |
| suff | A string of list of strings that are suffixes. Default is NULL. |
| squish | A boolean that tells whether to remove extra spaces in the output of paste_*() functions. Default is TRUE. |
| which | Tells which to keep, the prefix ("pref") or the suffix ("suff"). |
| from | The notation to switch away from. |
| to | The notation to switch to. |
| flip | A boolean that tells whether to also flip the notation. Default is FALSE. |

## Value

For notation_vec(), arrow_notation, and bracket_notation, a string vector with named items pref_start, pref_end, suff_start, and suff_end; For split_pref_suff(), a string list with named items pref and suff. For paste_pref_suff(), split_pref_suff(), and switch_notation(), a string list in notation format specified by various notation arguments, including from, and to. For keep_pref_suff, one of the prefix or suffix or a list of prefixes or suffixes.

## Examples

```
notation_vec()
arrow_notation
bracket_notation
split_pref_suff("a -> b", notation = arrow_notation)
# Or infer the notation (by default from notations_list)
split_pref_suff("a -> b")
split_pref_suff(c("a -> b", "c -> d", "e -> f"))
split_pref_suff(c("a -> b", "c -> d", "e -> f"), transpose = TRUE)
flip_pref_suff("a [b]", notation = bracket_notation)
# Infer notation
flip_pref_suff("a [b]")
get_pref_suff("a -> b", which = "suff")
```

```
switch_notation("a -> b", from = arrow_notation, to = bracket_notation)
# Infer notation and flip prefix and suffix
switch_notation("a -> b", to = bracket_notation, flip = TRUE)
# Also works for vectors
switch_notation(c("a -> b", "c -> d"),
    from = arrow_notation,
    to = bracket_notation)
# Functions can infer the correct notation and return multiple matches
infer_notation("a [to b]",
    allow_multiple = TRUE,
    choose_most_specific = FALSE)
# Or choose the most specific notation
infer_notation("a [to b]",
    allow_multiple = TRUE,
    choose_most_specific = TRUE)
# When setting the from notation, only that type of notation will be switched
switch_notation(c("a -> b", "c [to d]"),
    from = arrow_notation,
    to = bracket_notation)
# But if notations are inferred, all notations can be switched
switch_notation(c("a -> b", "c [to d]"), to = bracket_notation)
# A double-switch can be accomplished.
# In this first example, `RCLabels::first_dot_notation` is inferred.
switch_notation("a.b.c", to = arrow_notation)
# In this second example,
# it is easier to specify the `from' and `to` notations.
switch_notation("a.b.c", to = arrow_notation) %>%
    switch_notation(from = first_dot_notation, to = arrow_notation)
# "" can be used as an input
paste_pref_suff(pref = "a", suff = "", notation = RCLabels::from_notation)
```

```
split_noun_pp Split row and column labels into nouns and prepositional phrases
```

## Description

This function is similar to split_pref_suff() in that it returns a list. However, this function's list is more detailed than split_pref_suff(). The return value from this function is a list with the first named item being the prefix (with the name noun) followed by objects of prepositional phrases (with names being prepositions that precede the objects).

```
Usage
    split_noun_pp(
        labels,
    inf_notation = TRUE,
    notation = RCLabels::notations_list,
    choose_most_specific = FALSE,
    prepositions = RCLabels::prepositions_list
)
```

## Arguments

$$
\begin{array}{ll}
\text { labels } & \text { The row and column labels from which prepositional phrases are to be extracted. } \\
\text { inf_notation } & \begin{array}{l}
\text { A boolean that tells whether to infer notation for } x \text {. Default is TRUE. See infer_notation() } \\
\text { for details. }
\end{array} \\
\text { notation } & \begin{array}{l}
\text { The notation type to be used when extracting prepositions. Default is RCLabels: : notations_list, } \\
\text { meaning that the notation is inferred using infer_notation(). }
\end{array} \\
\text { choose_most_specific } \\
\text { A boolean that tells whether to choose the most specific notation from notation } \\
\text { when inferring notation. Default is FALSE so that a less specific notation can be } \\
\text { inferred. In combination with RCLabels: : notations_list, the default value } \\
\text { of FALSE means that RCLabels: : bracket_notation will be selected instead of } \\
\text { anything more specific, such as RCLabels: :from_notation. }
\end{array}
$$

## Details

Unlike split_pref_suff(), it does not make sense to have a transpose argument on split_noun_pp(). Labels may not have the same structure, e.g., they may have different prepositions.

## Value

A list of lists with items named noun and pp.

## Examples

```
# Specify the notation
split_noun_pp(c("a [of b in c]", "d [of e into f]"),
    notation = bracket_notation)
# Infer the notation via default arguments
split_noun_pp(c("a [of b in c]", "d [of e into f]"))
```

strip_label_part A convenience function to help splitting prefixes and suffixes

## Description

This function should only ever see a single label ( $x$ ) and a single notation.

## Usage

```
strip_label_part(x, notation, part, pattern_pref = "", pattern_suff = "")
```

## Arguments

X
notation
part
pattern_pref
pattern_suff

The label(s) to be split.
The notations to be used for each x .
The part of the label to work on, such as "pref_start", "pref_end", "suff_start", or "suff_end".
The prefix to a regex pattern to be used in gsub().
The suffix to a regex pattern to be used in gsub().

## Details

If notation is NULL, x is returned, unmodified.

## Value

A label shorn of the part to be stripped.
to_notation To notation

## Description

A description of to notation.

## Usage

to_notation

## Format

A vector of notational symbols that provides to ("a [to b]") notation.

## Examples

```
to_notation
```
