clifford-package Arbitrary Dimensional Clifford Algebras

## Description

A suite of routines for Clifford algebras, using the 'Map' class of the Standard Template Library. Canonical reference: Hestenes (1987, ISBN 90-277-1673-0, "Clifford algebra to geometric calculus"). Special cases including Lorentz transforms, quaternion multiplication, and Grassman algebra, are discussed. Conformal geometric algebra theory is implemented. Uses 'disordR' discipline.

clifford

## Examples

as.1vector(1:4)

```
as.1vector(1:4) * rcliff()
# Following from Ablamowicz and Fauser (see vignette):
x <- clifford(list(1:3,c(1,5,7,8,10)),c(4,-10)) + 2
y <- clifford(list(c(1,2,3,7),c(1,5,6,8),c(1,4,6,7)),c(4,1,-3)) - 1
x*y # signature irrelevant
```

allcliff

Clifford object containing all possible terms

## Description

The Clifford algebra on basis vectors $e_{1}, e_{2}, \ldots, e_{n}$ has $2^{n}$ independent multivectors. Function allcliff() generates a clifford object with a nonzero coefficient for each multivector.

## Usage

allcliff(n, grade)

## Arguments

$\mathrm{n} \quad$ Integer specifying dimension of underlying vector space
grade Grade of multivector to be returned. If missing, multivector contains every term of every grade $\leq n$

## Author(s)

Robin K. S. Hankin

## Examples

```
allcliff(6)
a <- allcliff(5)
a[] <- rcliff()*100
```

## antivector <br> Antivectors or pseudovectors

## Description

Antivectors or pseudovectors

## Usage

antivector(v, $\mathrm{n}=$ length(v))
as.antivector(v)
is.antivector (C, include.pseudoscalar=FALSE)

## Arguments

$v$ Numeric vector
$n \quad$ Integer specifying dimensionality of underlying vector space
C Clifford object
include.pseudoscalar
Boolean: should the pseudoscalar be considered an antivector?

## Details

An antivector is an $n$-dimensional Clifford object, all of whose terms are of grade $n-1$. An antivector has $n$ degrees of freedom. Function antivector $(v, n)$ interprets $v[i]$ as the coefficient of $e_{1} e_{2} \ldots e_{i-1} e_{i+1} \ldots e_{n}$.

Function as.antivector() is a convenience wrapper, coercing its argument to an antivector of minimal dimension (zero entries are interpreted consistently).
The pseudoscalar is a peculiar edge case. Consider:

```
    A <- clifford(list(c(1,2,3)))
    B <- A + clifford(list(c(1,2,4)))
> is.antivector(A)
[1] FALSE
> is.antivector(B)
[1] TRUE
> is.antivector(A,include.pseudoscalar=TRUE)
[1] TRUE
> is.antivector(B,include.pseudoscalar=TRUE)
[1] TRUE
```

One could argue that $A$ should be an antivector as it is a term in $B$, which is definitely an antivector. Use include.pseudoscalar=TRUE to ensure consistency in this case.

Compare as. 1 vector(), which returns a clifford object of grade 1 .

## Note

An antivector is always a blade.

## See Also

as. 1 vector

## Examples

```
antivector(1:5)
as.1vector(c(1,1,2)) %X% as.1vector(c(3,2,2))
c(1*2-2*2, 2*3-1*2, 1*2-1*3) # note sign of e_13
```

as.vector Coerce a clifford vector to a numeric vector

## Description

Given a clifford object with all terms of grade 1 , return the corresponding numeric vector

## Usage

\#\# S3 method for class 'clifford'
as.vector (x,mode = "any")

## Arguments

| $x$ | Object of class clifford |
| :--- | :--- |
| mode | ignored |

## Note

The awkward R idiom of this function is because the terms may be stored in any order; see the examples

## Author(s)

Robin K. S. Hankin

## See Also

```
numeric_to_clifford
```

## Examples

```
x <- clifford(list(6, 2, 9),1:3)
as.vector(x)
as.1vector(as.vector(x)) == x # should be TRUE
```

cartan Cartan map between clifford algebras

## Description

Cartan's map isomorphisms from $C l(p, q)$ to $C l(p-4, q+4)$ and $C l(p+4, q-4)$

## Usage

$\operatorname{cartan}(\mathrm{C}, \mathrm{n}=1)$
cartan_inverse(C, n = 1)

## Arguments

C Object of class clifford
$\mathrm{n} \quad$ Strictly positive integer

## Value

Returns an object of class clifford. The default value $\mathrm{n}=1$ maps $C l(4, q)$ to $C l(0, q+4)$ (cartan()) and $C l(0, q)$ to $C l(4, q-4)$.

## Examples

```
a <- rcliff(d=7) \# Cl(4,3)
b <- rcliff(d=7) \# Cl(4,3)
signature \((4,3) \quad \# e 1^{\wedge} 2=e 2^{\wedge} 2=e 3^{\wedge} 2=e 4^{\wedge} 2=+1 ; ~ e 5^{\wedge} 2=e 6^{\wedge} 2=e 7^{\wedge} 2=-1\)
ab <- a *b \# multiplication in \(\mathrm{Cl}(4,3)\)
signature \((0,7) \quad \#\) e1^2 \(=\ldots=e 7^{\wedge} 2=-1\)
cartan(a)*cartan(b) == cartan(ab) \# multiplication in \(\mathrm{Cl}(0,7)\); should be TRUE
signature(Inf) \# restore default
```

## clifford Create, coerce, and test for clifford objects

## Description

An object of class clifford is a member of a Clifford algebra. These objects may be added and multiplied, and have various applications in physics and mathematics.

## Usage

```
clifford(terms, coeffs=1)
is_ok_clifford(terms, coeffs)
as.clifford(x)
is.clifford(x)
nbits(x)
nterms(x)
## S3 method for class 'clifford'
dim(x)
```

## Arguments

| terms | A list of integer vectors with strictly increasing entries corresponding to the basis <br> vectors of the underlying vector space |
| :--- | :--- |
| coeffs | Numeric vector of coefficients |
| $x$ | Object of class clifford |

## Details

- Function clifford() is the formal creation mechanism for clifford objects
- Function as.clifford() is much more user-friendly and attempts to coerce a range of input arguments to clifford form
- Function nbits() returns the number of bits required in the low-level C routines to store the terms (this is the largest entry in the list of terms). For a scalar, this is zero and for the zero clifford object it (currently) returns zero as well although a case could be made for NULL
- Function nterms() returns the number of terms in the expression
- Function is_ok_clifford() is a helper function that checks for consistency of its arguments
- Function is.term() returns TRUE if all terms of its argument have the same grade

## Examples

```
(x <- clifford(list(1,2,1:4),1:3)) # Formal creation method
(y <- as.1vector(4:2))
(z <- rcliff(include.fewer=TRUE))
terms(x+100)
coeffs(z)
## Clifford objects may be added and multiplied:
x + y
x*y
```

const
The constant term of a Clifford object

## Description

Get and set the constant term of a clifford object.

## Usage

```
const(C,drop=TRUE)
is.real(C)
## S3 replacement method for class 'clifford'
const(x) <- value
```

## Arguments

$C, x \quad$ Clifford object
value Replacement value
drop Boolean, with default TRUE meaning to return the constant coerced to numeric, and FALSE meaning to return a (constant) Clifford object

## Details

Extractor method for specific terms. Function const() returns the constant element of a Clifford object. Note that const (C) returns the same as grade (C, 0), but is faster.

The R idiom in const<-() is slightly awkward:

```
> body(`const<-.clifford`)
{
    stopifnot(length(value) == 1)
    x <- x - const(x)
    return(x + value)
}
```

The reason that it is not simply return( $x$-const $(x)+$ value) or return $(x+v a l u e-c o n s t(x))$ is to ensure numerical accuracy; see examples.

## Author(s)

Robin K. S. Hankin

## See Also

grade, clifford, getcoeffs, is.zero

## Examples

```
X<- clifford(list(1,1:2,1:3,3:5),6:9)
X
X <- X + 1e300
X
const(X) # should be 1e300
const(X) <- 0.6
const(X) # should be 0.6, no numerical error
# compare naive approach:
X <- clifford(list(1,1:2,1:3,3:5),6:9)+1e300
X+0.6-const(X) # constant gets lost in the numerics
X <- clifford(list(1,1:2,1:3,3:5),6:9)+1e-300
X-const(X)+0.6 # answer correct by virtue of left-associativity
x <- 2+rcliff(d=3,g=3)
jj <- x*cliffconj(x)
is.real(jj*rev(jj)) # should be TRUE
```

drop Drop redundant information

## Description

Coerce constant Clifford objects to numeric

## Usage

drop( $x$ )

## Arguments

x
Clifford object

## Details

If its argument is a constant clifford object, coerce to numeric.

## Note

Many functions in the package take drop as an argument which, if TRUE, means that the function returns a dropped value.

## Author(s)

Robin K. S. Hankin

## See Also

```
grade,getcoeffs
```

## Examples

```
drop(as.clifford(5))
const(rcliff())
const(rcliff(),drop=FALSE)
```

```
even Even and odd clifford objects
```

## Description

A clifford object is even if every term has even grade, and odd if every term has odd grade.
Functions is.even() and is.odd() test a clifford object for evenness or oddness.
Functions evenpart() and oddpart() extract the even or odd terms from a clifford object, and we write $A_{+}$and $A_{-}$respectively; we have $A=A_{+}+A_{-}$

## Usage

```
is.even(C)
is.odd(C)
evenpart(C)
oddpart(C)
```

## Arguments

C
Clifford object

## Author(s)

Robin K. S. Hankin

## See Also

grade

## Examples

A <- rcliff()
A == evenpart(A) + oddpart(A) \# should be true

Extract.clifford Extract or Replace Parts of a clifford

## Description

Extract or replace subsets of cliffords.

## Usage

```
## S3 method for class 'clifford'
C[index, ...]
## S3 replacement method for class 'clifford'
C[index, ...] <- value
coeffs(x)
coeffs(x) <- value
list_modifier(B)
getcoeffs(C, B)
```

## Arguments

| $C, x$ | A clifford object |
| :--- | :--- |
| index | elements to extract or replace |
| value | replacement value |
| B | A list of integer vectors, terms |
| $\ldots$ | Further arguments |

## Details

Extraction and replacement methods. The extraction method uses getcoeffs() and the replacement method uses low-level helper function c_overwrite().
In the extraction function a[index], if index is a list, further arguments are ignored; if not, the dots are used. If index is a list, its elements are interpreted as integer vectors indicating which terms to be extracted (even if it is a disord object). If index is a disord object, standard consistency rules are applied. The extraction methods are designed so that idiom such as $a[\operatorname{coeffs}(a)>3]$ works.
For replacement methods, the standard use-case is $a[i]<-b$ in which argument $i$ is a list of integer vectors and $b$ a length-one numeric vector. Otherwise, to manipulate parts of a clifford object, use coeffs $(a)<-$ value; this effectively leverages disord formalism. Idiom such as a[coeffs(a)<2] $<-\theta$ is not currently implemented (to do this, use coeffs(a)[coeffs (a)<2] <- 0). Replacement
 methods are not yet finalised and not yet fully integrated with the disordR package.

Idiom such as $a[]<-b$ follows the spray package. If $b$ is a length-one scalar, then coeffs(a) <$b$ has the same effect as $a[]<-b$.

Functions terms() [see term.Rd] and coeffs() extract the terms and coefficients from a clifford object. These functions return disord objects but the ordering is consistent between them (an extended discussion of this phenomenon is presented in the mvp package).
Function coeffs<-() (idiom coeffs $(a)<-b)$ sets all coefficients of a to b. This has the same effect as a[]$<-\mathrm{b}$.
Extraction and replacement methods treat 0 specially, translating it (via list_modifier()) to numeric(0).

Extracting or replacing a list with a repeated elements is usually a Bad Idea (tm). However, if option warn_on_repeats is set to FALSE, no warning will be given (and the coefficient will be the sum of the coefficients of the term; see the examples).

Function getcoeffs() is a lower-level helper function that lacks the succour offered by [.clifford(). It returns a numeric vector [not a disord object: the order of the elements is determined by the order of argument $B$ ]. Compare standard extraction, eg a[index], which returns a clifford object.

## See Also

```
Ops.clifford,clifford,term
```

## Examples

```
A <- clifford(list(1,1:2,1:3),1:3)
B <- clifford(list(1:2,1:6),c(44,45))
A[1,c(1,3,4)]
A[2:3, 4] <- 99
A[] <- B
# clifford(list(1,1:2,1:2),1:3) # would give a warning
options("warn_on_repeats" = FALSE)
clifford(list(1,1:2,1:2),1:3) # works; 1e1 + 5e_12
options("warn_on_repeats" = TRUE) # return to default behaviour.
```

```
grade The grade of a clifford object
```

## Description

The grade of a term is the number of basis vectors in it.

## Usage

grade( $C, n$, drop=TRUE)
grade (C, n) <- value
grades(x)
gradesplus(x)
gradesminus(x)
gradeszero(x)

## Arguments

| $C, x$ | Clifford object |
| :--- | :--- |
| $n$ | Integer vector specifying grades to extract |
| value | Replacement value, a numeric vector |
| drop | Boolean, with default TRUE meaning to coerce a constant Clifford object to nu- <br> meric, and FALSE meaning not to |

## Details

A term is a single expression in a Clifford object. It has a coefficient and is described by the basis vectors it comprises. Thus $4 e_{234}$ is a term but $e_{3}+e_{5}$ is not.
The grade of a term is the number of basis vectors in it. Thus the grade of $e_{1}$ is 1 , and the grade of $e_{125}=e_{1} e_{2} e_{5}$ is 3 . The grade operator $\langle\cdot\rangle_{r}$ is used to extract terms of a particular grade, with

$$
A=\langle A\rangle_{0}+\langle A\rangle_{1}+\langle A\rangle_{2}+\cdots=\sum_{r}\langle A\rangle_{r}
$$

for any Clifford object $A$. Thus $\langle A\rangle_{r}$ is said to be homogenous of grade $r$. Hestenes sometimes writes subscripts that specify grades using an overbar as in $\langle A\rangle_{\bar{r}}$. It is conventional to denote the zero-grade object $\langle A\rangle_{0}$ as simply $\langle A\rangle$.
We have

$$
\langle A+B\rangle_{r}=\langle A\rangle_{r}+\langle B\rangle_{r} \quad\langle\lambda A\rangle_{r}=\lambda\langle A\rangle_{r} \quad\left\langle\langle A\rangle_{r}\right\rangle_{s}=\langle A\rangle_{r} \delta_{r s}
$$

Function grades() returns an (unordered) vector specifying the grades of the constituent terms. Function grades<-() allows idiom such as grade ( $x, 1: 2$ ) <- 7 to operate as expected [here to set all coefficients of terms with grades 1 or 2 to value 7].
Function gradesplus() returns the same but counting only basis vectors that square to +1 , and gradesminus() counts only basis vectors that square to -1 . Function signature() controls which basis vectors square to +1 and which to -1 .
From Perwass, page 57, given a bilinear form

$$
\langle\mathbf{x}, \mathbf{x}\rangle=x_{1}^{2}+x_{2}^{2}+\cdots+x_{p}^{2}-x_{p+1}^{2}-\cdots-x_{p+q}^{2}
$$

and a basis blade $e_{A}$ with $A \subseteq\{1, \ldots, p+q\}$, then

$$
\begin{gathered}
\operatorname{gr}\left(e_{A}\right)=|\{a \in A: 1 \leq a \leq p+q\}| \\
\operatorname{gr}_{+}\left(e_{A}\right)=|\{a \in A: 1 \leq a \leq p\}| \\
\operatorname{gr}_{-}\left(e_{A}\right)=|\{a \in A: p<a \leq p+q\}|
\end{gathered}
$$

Function gradeszero() counts only the basis vectors squaring to zero (I have not seen this anywhere else, but it is a logical suggestion).
If the signature is zero, then the Clifford algebra reduces to a Grassman algebra and products match the wedge product of exterior calculus. In this case, functions gradesplus() and gradesminus() return NA.

Function grade ( $\mathrm{C}, \mathrm{n}$ ) returns a clifford object with just the elements of grade g , where $\mathrm{g} \% \mathrm{in} \% \mathrm{n}$.
The zero grade term, grade ( $C, 0$ ), is given more naturally by const ( $C$ ).
Function c_grade() is a helper function that is documented at Ops.clifford.Rd.

## Note

In the C code, "term" has a slightly different meaning, referring to the vectors without the associated coefficient.

## Author(s)

Robin K. S. Hankin

## References

C. Perwass 2009. "Geometric algebra with applications in engineering". Springer.

## See Also

signature, const

## Examples

```
a <- clifford(sapply(seq_len(7),seq_len),seq_len(7))
a
grades(a)
grade(a,5)
signature(2,2)
x <- rcliff()
drop(gradesplus(x) + gradesminus(x) + gradeszero(x) - grades(x))
a <- rcliff()
a == Reduce(`+`,sapply(unique(grades(a)),function(g){grade(a,g)}))
```

## homog Homogenous Clifford objects

## Description

A clifford object is homogenous if all its terms are the same grade. A scalar (including the zero clifford object) is considered to be homogenous. This ensures that is.homog (grade( $\mathrm{C}, \mathrm{n}$ ) ) always returns TRUE.

## Usage

is.homog (C)

## Arguments

C
Object of class clifford

## Note

Nonzero homogenous clifford objects have a multiplicative inverse.

## Author(s)

Robin K. S. Hankin

## Examples

is.homog(rcliff())
is.homog(rcliff(include.fewer=FALSE))

## horner Horner's method

## Description

Horner's method for Clifford objects

## Usage

horner ( $\mathrm{P}, \mathrm{v}$ )

## Arguments

| $P$ | Multivariate polynomial |
| :--- | :--- |
| V | Numeric vector of coefficients |

## Details

Given a polynomial

$$
p(x)=a_{0}+a_{1}+a_{2} x^{2}+\cdots+a_{n} x^{n}
$$

it is possible to express $p(x)$ in the algebraically equivalent form

$$
p(x)=a_{0}+x\left(a_{1}+x\left(a_{2}+\cdots+x\left(a_{n-1}+x a_{n}\right) \cdots\right)\right)
$$

which is much more efficient for evaluation, as it requires only $n$ multiplications and $n$ additions, and this is optimal. The output of horner() depends on the signature().

## Note

Horner's method is not as cool for Clifford objects as it is for (e.g.) multivariate polynomials or freealg objects. This is because powers of Clifford objects don't get more complicated as the power increases.

## Author(s)

Robin K. S. Hankin

## Examples

```
horner(1+e(1:3)+e(2:3), 1:6)
rcliff() |> horner(1:4)
```

## Description

An involution is a function that is its own inverse, or equivalently $f(f(x))=x$. There are several important involutions on Clifford objects; these commute past the grade operator with $f\left(\langle A\rangle_{r}\right)=$ $\langle f(A)\rangle_{r}$ and are linear: $f(\alpha A+\beta B)=\alpha f(A)+\beta f(B)$.
The dual is documented here for convenience, even though it is not an involution (applying the dual four times is the identity).

- The reverse $A^{\sim}$ is given by rev() (both Perwass and Dorst use a tilde, as in $\tilde{A}$ or $A^{\sim}$. However, both Hestenes and Chisholm use a dagger, as in $A^{\dagger}$. This page uses Perwass's notation). The reverse of a term written as a product of basis vectors is simply the product of the same basis vectors but written in reverse order. This changes the sign of the term if the number of basis vectors is 2 or 3 (modulo 4). Thus, for example, $\left(e_{1} e_{2} e_{3}\right)^{\sim}=e_{3} e_{2} e_{1}=-e_{1} e_{2} e_{3}$ and $\left(e_{1} e_{2} e_{3} e_{4}\right)^{\sim}=e_{4} e_{3} e_{2} e_{1}=+e_{1} e_{2} e_{3} e_{4}$. Formally, if $X=e_{i_{1}} \ldots e_{i_{k}}$, then $\tilde{X}=e_{i_{k}} \ldots e_{i_{1}}$.

$$
\left\langle A^{\sim}\right\rangle_{r}=\widetilde{\langle A\rangle_{r}}=(-1)^{r(r-1) / 2}\langle A\rangle_{r}
$$

Perwass shows that $\langle A B\rangle_{r}=(-1)^{r(r-1) / 2}\langle\tilde{B} \tilde{A}\rangle_{r}$.

- The Conjugate $A^{\dagger}$ is given by Conj() (we use Perwass's notation, def 2.9 p 59 ). This depends on the signature of the Clifford algebra; see grade.Rd for notation. Given a basis blade $e_{A}$ with $A \subseteq\{1, \ldots, p+q\}$, then we have $e_{A}^{\dagger}=(-1)^{m} e_{A}{ }^{\sim}$, where $m=\operatorname{gr}_{-}(A)$. Alternatively, we might say

$$
\left(\langle A\rangle_{r}\right)^{\dagger}=(-1)^{m}(-1)^{r(r-1) / 2}\langle A\rangle_{r}
$$

where $m=\mathrm{gr}_{-}\left(\langle A\rangle_{r}\right)$ [NB I have changed Perwass's notation].

- The main (grade) involution or grade involution $\widehat{A}$ is given by gradeinv(). This changes the sign of any term with odd grade:

$$
\widehat{\langle A\rangle_{r}}=(-1)^{r}\langle A\rangle_{r}
$$

(I don't see this in Perwass or Hestenes; notation follows Hitzer and Sangwine). It is a special case of grade negation.

- The grade $r$-negation $A_{\bar{r}}$ is given by neg(). This changes the sign of the grade $r$ component of $A$. It is formally defined as $A-2\langle A\rangle_{r}$ but function neg() uses a more efficient method. It is possible to negate all terms with specified grades, so for example we might have $\langle A\rangle_{\{1,2,5\}}=$ $A-2\left(\langle A\rangle_{1}+\langle A\rangle_{2}+\langle A\rangle_{5}\right)$ and the R idiom would be neg $(\mathrm{A}, \mathrm{c}(1,2,5))$. Note that Hestenes uses " $A_{\bar{r}}$ " to mean the same as $\langle A\rangle_{r}$.
- The Clifford conjugate $\bar{A}$ is given by cliffconj(). It is distinct from conjugation $A^{\dagger}$, and is defined in Hitzer and Sangwine as

$$
\overline{\langle A\rangle_{r}}=(-1)^{r(r+1) / 2}\langle A\rangle_{r} .
$$

- The dual $C^{*}$ of a clifford object $C$ is given by dual $(\mathrm{C}, \mathrm{n})$; argument n is the dimension of the underlying vector space. Perwass gives

$$
C^{*}=C I^{-1}
$$

where $I=e_{1} e_{2} \ldots e_{n}$ is the unit pseudoscalar [note that Hestenes uses $I$ to mean something different]. The dual is sensitive to the signature of the Clifford algebra and the dimension of the underlying vector space.

## Usage

```
## S3 method for class 'clifford'
rev(x)
## S3 method for class 'clifford'
Conj(z)
cliffconj(z)
neg(C,n)
gradeinv(C)
```

## Arguments

C, $x, z$
n

## Clifford object

Integer vector specifying grades to be negated in neg()

## Author(s)

Robin K. S. Hankin

## See Also

grade

## Examples

```
x <- rcliff()
x
rev(x)
A <- rblade(g=3)
B <- rblade(g=4)
rev(A %^% B) == rev(B) %^% rev(A) # should be TRUE
rev(A * B) == rev(B) * rev(A) # should be TRUE
a <- rcliff()
dual(dual(dual(dual(a,8),8),8),8) == a # should be TRUE
```

## lowlevel Low-level helper functions for clifford objects

## Description

Helper functions for clifford objects, written in C using the STL map class.

## Usage

```
c_identity(L, p, m)
c_grade(L, c, m, n)
c_add(L1, c1, L2, c2, m)
c_multiply(L1, c1, L2, c2, m, sig)
c_power(L, c, m, p, sig)
```

```
c_equal(L1, c1, L2, c2, m)
c_overwrite(L1, c1, L2, c2, m)
c_cartan(L, c, m, n)
c_cartan_inverse(L, c, m, n)
```

## Arguments

| $\mathrm{L}, \mathrm{L} 1, \mathrm{~L} 2$ | Lists of terms |
| :--- | :--- |
| $\mathrm{c} 1, \mathrm{c} 2, \mathrm{c}$ | Numeric vectors of coefficients |
| m | Maximum entry of terms |
| n | Grade to extract |
| p | Integer power |
| sig | Two positive integers, $p$ and $q$, representing the number of +1 and -1 terms on <br> the main diagonal of quadratic form |

## Details

The functions documented here are low-level helper functions that wrap the C code. They are called by functions like clifford_plus_clifford(), which are themselves called by the binary operators documented at Ops.clifford.Rd.

Function clifford_inverse() is problematic as nonnull blades always have an inverse; but function is.blade() is not yet implemented. Blades (including null blades) have a pseudoinverse, but this is not implemented yet either.

## Value

The high-level functions documented here return an object of clifford. But don't use the low-level functions.

## Author(s)

Robin K. S. Hankin

See Also
Ops.clifford
magnitude Magnitude of a clifford object

## Description

Following Perwass, the magnitude of a multivector is defined as

$$
\|A\|=\sqrt{A * A}
$$

Where $A * A$ denotes the Euclidean scalar product eucprod(). Recall that the Euclidean scalar product is never negative (the function body is sqrt(abs(eucprod(z))); the abs() is needed to avoid numerical roundoff errors in eucprod() giving a negative value).

## Usage

\#\# S3 method for class 'clifford'
$\operatorname{Mod}(z)$

## Arguments

z
Clifford objects

## Note

If you want the square, $\|A\|^{2}$ and not $\|A\|$, it is faster and more accurate to use eucprod(A), because this avoids a needless square root.

There is a nice example of scalar product at rcliff.Rd.

## Author(s)

Robin K. S. Hankin

Ops.clifford, Conj,rcliff
```

## Examples

```
Mod(rcliff())
# Perwass, p68, asserts that if A is a k-blade, then (in his notation)
# AA == A*A.
# In package idiom, A*A == A %star% A:
A <- rcliff()
Mod(A*A - A %star% A) # meh
A <- rblade()
Mod(A*A - A %star% A) # should be small
```

minus $\quad$ Take the negative of a vector

## Description

Very simple function that takes the negative of a vector, here so that idiom such as coeffs(z)[gradesminus(z)\%\%2!=0] \%<>\% minus
works as intended (this taken from Conj. clifford()).

## Usage

$$
\text { minus }(x)
$$

## Arguments

$x \quad$ Any vector or disord object

## Value

Returns a vector or disord

## Author(s)

Robin K. S. Hankin

## numeric_to_clifford Coercion from numeric to Clifford form

## Description

Given a numeric value or vector, return a Clifford algebra element

## Usage

```
numeric_to_clifford(x)
as.1vector(x)
is.1vector(x)
scalar(x=1)
as.scalar(x=1)
is.scalar(C)
basis(n,x=1)
e(n,x=1)
pseudoscalar(n,x=1)
as.pseudoscalar(n,x=1)
is.pseudoscalar(C)
```

## Arguments

| $x$ | Numeric vector |
| :--- | :--- |
| $n$ | Integer specifying dimensionality of underlying vector space |
| $c$ | Object possibly of class Clifford |

## Details

Function as.scalar() takes a length-one numeric vector and returns a Clifford scalar of that value (to extract the scalar component of a multivector, use const()).
Function is.scalar() is a synonym for is.real() which is documented at const.Rd.
Function as.1vector() takes a numeric vector and returns the linear sum of length-one blades with coefficients given by $x$; function is. 1 vector () returns TRUE if every term is of grade 1 .

Function pseudoscalar ( n ) returns a pseudoscalar of dimensionality n and function is. pseudoscalar() checks for a Clifford object being a pseudoscalar.

Function numeric_to_vector() dispatches to either as.scalar() for length-one vectors or as.1vector() if the length is greater than one

Function basis() returns a wedge product of basis vectors; function e() is a synonym. There is special dispensation for zero, so e(0) returns the Clifford scalar 1.
Function antivector() should arguably be described here but is actually documented at antivector.Rd.

clifford_inverse(C)
cliffdotprod(C1,C2)
fatdot(C1,C2)
lefttick(C1,C2)
```

righttick(C1, C2)
wedge(C1,C2)
scalprod(C1, C2=rev(C1), drop=TRUE)
eucprod(C1,C2=C1,drop=TRUE)
maxyterm(C1, C2=as.clifford(0))
C1 \%.\% C2
C1 \% dot\% C2
C1 \%^\% C2
C1 \%X\% C2
C1 \%star\% C2
C1 \% \% C2
C1 \%euc\% C2
C1 \% \% C2
C1 \%_|\% C2
C1 \%|_\% C2

## Arguments

e1, e2, C, C1, C2 Objects of class clifford or coerced if needed
$x \quad$ Scalar, length one numeric vector
drop Boolean, with default TRUE meaning to return the constant coerced to numeric, and FALSE meaning to return a (constant) Clifford object

## Details

The function Ops.clifford() passes unary and binary arithmetic operators "+", "-", "*", "/" and " $\wedge$ " to the appropriate specialist function. Function maxyterm() returns the maximum index in the terms of its arguments.
The package has several binary operators:

| Geometric product | $A * B=\operatorname{geoprod}(A, B)$ | $A B=\sum_{r, s}\langle A\rangle_{r}\langle B\rangle_{s}$ |
| :---: | :---: | :---: |
| Inner product | A \% \% B = cliffdotprod ( $A, B$ ) | $A \cdot B=\sum_{\substack{r \neq 0 \\ s \neq 0}}\left\langle\langle A\rangle_{r}\langle B\rangle_{s}\right\rangle_{\|s-r\|}$ |
| Outer product | $A \% \wedge \% B=$ wedge ( $A, B$ ) | $A \wedge B=\sum\left\langle\langle A\rangle_{r}\langle B\rangle_{s}\right\rangle_{s+r}$ |
| Fat dot product | A \%\%\% $\mathrm{B}=\mathrm{fatdot}(\mathrm{A}, \mathrm{B})$ | $A \bullet B=\sum^{r, s}\left\langle\langle A\rangle_{r}\langle B\rangle_{s}\right\rangle_{\mid s-}$ |
| Left contraction | A \%_\|\% B = lefttick(A, B | $A\rfloor B=\sum^{r, s}\left\langle\langle A\rangle_{r}\langle B\rangle_{s}\right\rangle_{s}$ |
| Right contraction | A \% \|_\% B = righttick (A, B | $A\left\lfloor B=\sum^{r, s}\left\langle\langle A\rangle_{r}\langle B\rangle_{s}\right\rangle_{r-s}\right.$ |
| Cross product | A \% X\% B $=\operatorname{cross}(\mathrm{A}, \mathrm{B})$ | $A \times B=\frac{1}{2}(A B-B A)$ |
| Scalar product | A \%star\% B = star (A, B | $A * B=\sum\left\langle\langle A\rangle_{r}\langle B\rangle_{s}\right\rangle_{0}$ |
| Euclidean product | A \%euc\% B = eucprod(A, B | $A \star B=\stackrel{r, s}{A *} * B^{\dagger}$ |

In R idiom, the geometric product geoprod (. . .) has to be indicated with a " $\star$ " (as in $\mathrm{A} * \mathrm{~B}$ ) and so the binary operator must be \%*\%: we need a different idiom for scalar product, which is why \%star\% is used.

Because geometric product is often denoted by juxtaposition, package idiom includes a \% \% b for geometric product.

Binary operator \%dot\% is a synonym for \%. \%, which causes problems for rmarkdown.
Function clifford_inverse() returns an inverse for nonnull Clifford objects $C l(p, q)$ for $p+q \leq$ 5 , and a few other special cases. The functionality is problematic as nonnull blades always have an inverse; but function is.blade() is not yet implemented. Blades (including null blades) have a pseudoinverse, but this is not implemented yet either.
The scalar product of two clifford objects is defined as the zero-grade component of their geometric product:

$$
A * B=\langle A B\rangle_{0} \quad \text { NB: notation used by both Perwass and Hestenes }
$$

In package idiom the scalar product is given by A \%star\% B or scalprod (A, B). Hestenes and Perwass both use an asterisk for scalar product as in " $A * B$ ", but in package idiom, the asterisk is reserved for geometric product.
Note: in the package, $A * B$ is the geometric product.
The Euclidean product (or Euclidean scalar product) of two clifford objects is defined as

$$
A \star B=A * B^{\dagger}=\left\langle A B^{\dagger}\right\rangle_{0} \quad \text { Perwass }
$$

where $B^{\dagger}$ denotes Conjugate [as in Conj(a)]. In package idiom the Euclidean scalar product is given by eucprod (A, B) or $A$ \%euc\% B, both of which return $A * \operatorname{Conj}(B)$.

Note that the scalar product $A * A$ can be positive or negative [that is, $\mathrm{A} \%$ star\% A may be any sign], but the Euclidean product is guaranteed to be non-negative [that is, $\mathrm{A} \% \mathrm{euc} \mathrm{\%} \mathrm{~A}$ is always positive or zero].
Dorst defines the left and right contraction (Chisholm calls these the left and right inner product) as $A\rfloor B$ and $A\lfloor B$. See the vignette for more details.
Division, as in idiom $x / y$, is defined as $x * c$ lifford_inverse( $y$ ). Function clifford_inverse() uses the method set out by Hitzer and Sangwine but is limited to $p+q \leq 5$.

Many of the functions documented here use low-level helper functions that wrap C code. For example, fatdot() uses c_fatdotprod(). These are documented at lowlevel.Rd.

## Value

The high-level functions documented here return a clifford object. The low-level functions are not really intended for the end-user.

## Note

In the clifford package the caret " "» is reserved for multiplicative powers, as in $A^{\wedge} 3=A * A * A$. All the different Clifford products have binary operators for convenience including the wedge product $\% \wedge \%$. Compare the stokes package, where multiplicative powers do not really make sense and $\mathrm{A}^{\wedge} \mathrm{B}$ is interpreted as a wedge product of differential forms $A$ and $B$. In stokes, the wedge product is the sine qua non for the whole package and needs a terse idiomatic representation (although there $A \% \wedge \%$ returns the wedge product too).

## Author(s)

Robin K. S. Hankin

## References

E. Hitzer and S. Sangwine 2017. "Multivector and multivector matrix inverses in real Clifford algebras". Applied Mathematics and Computation 311:375-389

## Examples

```
u <- rcliff(5)
v <- rcliff(5)
w <- rcliff(5)
u
v
u*v
u+(v+w) == (u+v)+w # should be TRUE by associativity of "+"
u* (v*w) == (u*v)*w # should be TRUE by associativity of "*"
u*(v+w) == u*v + u*w # should be TRUE by distributivity
# Now if x,y are _vectors_ we have:
x <- as.1vector(sample(5))
y <- as.1vector(sample(5))
x*y == x%.%y + x%^%y
x %^% y == x %^% (y + 3*x)
x %^% y == (x*y-x*y)/2 # should be TRUE
# above are TRUE for x,y vectors (but not for multivectors, in general)
## Inner product "%.%" is not associative:
x <- rcliff(5,g=2)
y <- rcliff(5,g=2)
z <- rcliff(5,g=2)
x %.% (y %.% z) == (x %.% y) %.% z
## Other products should work as expected:
x %|_% y ## left contraction
x %_|% y ## right contraction
x %o% y ## fat dot product
```

print

## Description

Print methods for Clifford algebra

## Usage

```
## S3 method for class 'clifford'
print(x,...)
## S3 method for class 'clifford'
as.character(x,...)
catterm(a)
```

## Arguments

$x \quad$ Object of class clifford in the print method
... Further arguments, currently ignored
a Integer vector representing a term

Note
The print method does not change the internal representation of a clifford object, which is a twoelement list, the first of which is a list of integer vectors representing terms, and the second is a numeric vector of coefficients.
The print method is sensitive to the value of option separate. If FALSE (the default), the method prints in a compact form, as in e_134. The indices of the basis vectors are separated with option basissep which is usually NULL but if $n>9$, then setting options("basissep" $=$ ",") might look good as it will print $\mathrm{e}_{-} 10,11,12$ instead of $\mathrm{e}_{-} 101112$. If separate is TRUE, the method prints the basis vectors separately, as in e1 e3 e4.

Function as.character.clifford() is also sensitive to these options. The print method has special dispensation for length-zero clifford objects. Function catterm() is a low-level helper function.

a # marginally better
options("separate" = FALSE)
options(basissep=",")
a # clearer; YMMV
options(basissep = NULL) # restore default
```

```
quaternion Quaternions using Clifford algebras
```

## Description

Converting quaternions to and from Clifford objects is not part of the package but functionality and a short discussion is included in inst/quaternion_clifford.Rmd.

## Details

Given a quaternion $a+b i+c j+d k$, one may identify $i$ with $-e_{12}, j$ with $-e_{13}$, and $k$ with $-e_{23}$ (the constant term is of course $e_{0}$ ).

## Note

A different mapping, from the quaternions to $C l(0,2)$ is given at signature. Rd.

> signature

## rcliff Random clifford objects

## Description

Random Clifford algebra elements, intended as quick "get you going" examples of clifford objects

## Usage

rcliff(n=9, d=6, g=4, include.fewer=TRUE)
rblade(d=7, g=3)

## Arguments

n Number of terms
d Dimensionality of underlying vector space
$g \quad$ Maximum grade of any term
include.fewer Boolean, with FALSE meaning to return a clifford object comprising only terms of grade $g$, and default TRUE meaning to include terms with grades less than $g$ (including a term of grade zero, that is, a scalar)

## Details

Function rcliff() gives a quick nontrivial Clifford object, typically with terms having a range of grades (see 'grade.Rd'); argument include.fewer=FALSE ensures that all terms are of the same grade.
Function rblade() gives a Clifford object that is a blade (see 'term. Rd'). It returns the wedge product of a number of 1-vectors, for example $\left(e_{1}+2 e_{2}\right) \wedge\left(e_{1}+3 e_{5}\right)$.
Perwass gives the following lemma:
Given blades $A_{\langle r\rangle}, B_{\langle s\rangle}, C_{\langle t\rangle}$, then

$$
\left\langle A_{\langle r\rangle} B_{\langle s\rangle} C_{\langle t\rangle}\right\rangle_{0}=\left\langle C_{\langle t\rangle} A_{\langle r\rangle} B_{\langle s\rangle}\right\rangle_{0}
$$

In the proof he notes in an intermediate step that

$$
\left\langle A_{\langle r\rangle} B_{\langle s\rangle}\right\rangle_{t} * C_{\langle t\rangle}=C_{\langle t\rangle} *\left\langle A_{\langle r\rangle} B_{\langle s\rangle}\right\rangle_{t}=\left\langle C_{\langle t\rangle} A_{\langle r\rangle} B_{\langle s\rangle}\right\rangle_{0}
$$

Package idiom is shown in the examples.

## Note

If the grade exceeds the dimensionality, $g>d$, then the result is arguably zero; $\operatorname{rcliff}()$ returns an error.

## Author(s)

Robin K. S. Hankin

x1*(x2*x3) == (x1*x2)*x3 # should be TRUE
rblade()
# We can invert blades easily:
a <- rblade()
ainv <- rev(a)/scalprod(a)
zap(a*ainv) # 1 (to numerical precision)
zap(ainv*a) # 1 (to numerical precision)
```

```
# Perwass 2009, lemma 3.9:
A <- rblade(d=9,g=4)
B <- rblade(d=9,g=5)
C <- rblade(d=9,g=6)
grade(A*B*C,0)-grade(C*A*B,0) # zero to numerical precision
# Intermediate step
x1 <- grade(A*B,3) %star% C
x2 <- C %star% grade(A*B,3)
x3 <- grade(C*A*B,0)
max(x1,x2,x3) - min(x1,x2,x3) # zero to numerical precision
```

```
signature The signature of the Clifford algebra
```

## Description

Getting and setting the signature of the Clifford algebra

## Usage

```
signature(p,q=0)
is_ok_sig(s)
showsig(s)
## S3 method for class 'sigobj'
print(x,...)
```

## Arguments

$s, p, q$
Integers, specifying number of positive elements on the diagonal of the quadratic form, with $s=c(p, q)$
x
Object of class sigobj
.. Further arguments, currently ignored

## Details

The signature functionality is modelled on lorentz: : sol () which gets and sets the speed of light.
Clifford algebras require a bilinear form on $R^{n}\langle\cdot, \cdot\rangle$, usually written

$$
\langle\mathbf{x}, \mathbf{x}\rangle=x_{1}^{2}+x_{2}^{2}+\cdots+x_{p}^{2}-x_{p+1}^{2}-\cdots-x_{p+q}^{2}
$$

where $p+q=n$. With this quadratic form the vector space is denoted $R^{p, q}$ and we say that $(p, q)$ is the signature of the bilinear form $\langle\cdot, \cdot\rangle$. This gives rise to the Clifford algebra $C_{p, q}$.

If the signature is $(p, q)$, then we have

$$
e_{i} e_{i}=+1(\text { if } 1 \leq i \leq p),-1(\text { if } p+1 \leq i \leq p+q), 0(\text { if } i>p+q) .
$$

Note that $(p, 0)$ corresponds to a positive-semidefinite quadratic form in which $e_{i} e_{i}=+1$ for all $i \leq p$ and $e_{i} e_{i}=0$ for all $i>p$. Similarly, $(0, q)$ corresponds to a negative-semidefinite quadratic form in which $e_{i} e_{i}=-1$ for all $i \leq q$ and $e_{i} e_{i}=0$ for all $i>q$.

Package idiom for a strictly positive-definite quadratic form would be to specify infinite $p$ [in which case $q$ is irrelevant] and for a strictly negative-definite quadratic form we would need $p=0, q=\infty$.
If we specify $e_{i} e_{i}=0$ for all $i$, then the operation reduces to the wedge product of a Grassman algebra. Package idiom for this is to set $p=q=0$, but this is not recommended: use the stokes package for Grassman algebras, which is much more efficient and uses nicer idiom.
Function signature $(p, q)$ returns the signature silently; but setting option show_signature to TRUE makes signature() have the side-effect of calling showsig(), which changes the default prompt to display the signature, much like showSOL in the lorentz package. There is special dispensation for "infinite" $p$ or $q$.
Calling signature() [that is, with no arguments] returns an object of class sigobj with elements corresponding to $p$ and $q$. The sigobj class ensures that a near-infinite integer such as .Machine\$integer.max will be printed as "Inf" rather than, for example, "2147483647".
Function is_ok_sig() is a helper function that checks for a proper signature.

## Author(s)

Robin K. S. Hankin

## Examples

```
signature()
e(1)^2
e(2)^2
signature(1)
e(1)^2
e(2)^2 # note sign
signature(3,4)
sapply(1:10,function(i){drop(e(i)^2)})
signature(Inf) # restore default
```

\# Nice mapping from $\mathrm{Cl}(0,2)$ to the quaternions (loading clifford and
\# onion simultaneously is discouraged):
\# library("onion")
\# signature(0,2)
\# Q1 <- rquat(1)
\# Q2 <- rquat(1)

```
# f <- function(H){Re(H)+i(H)*e(1)+j(H)*e(2)+k(H)*e(1:2)}
# f(Q1)*f(Q2) - f(Q1*Q2) # zero to numerical precision
# signature(Inf)
```

```
summary.clifford Summary methods for clifford objects
```

## Description

Summary method for clifford objects, and a print method for summaries.

## Usage

```
## S3 method for class 'clifford'
summary(object, ...)
## S3 method for class 'summary.clifford'
print(x, ...)
first_n_last(x)
```

## Arguments

$\begin{array}{ll}\text { object }, \mathrm{x} & \text { Object of class clifford } \\ \ldots & \text { Further arguments, currently ignored }\end{array}$

## Details

Summary of a clifford object. Note carefully that the "typical terms" are implementation specific. Function first_n_last() is a helper function.

## Examples

```
summary(rcliff())
```

```
term Deal with terms
```

## Description

By basis vector, I mean one of the basis vectors of the underlying vector space $R^{n}$, that is, an element of the set $\left\{e_{1}, \ldots, e_{n}\right\}$. A term is a wedge product of basis vectors (or a geometric product of linearly independent basis vectors), something like $e_{12}$ or $e_{12569}$. Sometimes I use the word "term" to mean a wedge product of basis vectors together with its associated coefficient: so $7 e_{12}$ would be described as a term.

From Perwass: a blade is the outer product of a number of 1-vectors (or, equivalently, the wedge product of linearly independent 1-vectors). Thus $e_{12}=e_{1} \wedge e_{2}$ and $e_{12}+e_{13}=e_{1} \wedge\left(e_{2}+e_{3}\right)$ are blades, but $e_{12}+e_{34}$ is not.

Function rblade(), documented at 'rcliff.Rd', returns a random blade.
Function is.blade() is not currently implemented: there is no easy way to detect whether a Clifford object is a product of 1 -vectors.

## Usage

```
terms(x)
```

is.blade(x)
is.basisblade(x)

## Arguments

## x <br> Object of class clifford

## Details

- Functions terms() and coeffs() are the extraction methods. These are unordered vectors but the ordering is consistent between them (an extended discussion of this phenomenon is presented in the mvp package).
- Function term() returns a clifford object that comprises a single term with unit coefficient.
- Function is.basisterm() returns TRUE if its argument has only a single term, or is a nonzero scalar; the zero clifford object is not considered to be a basis term.

zap Zap small values in a clifford object

## Description

Generic version of zapsmall()

## Usage

zap(x, drop=TRUE, digits = getOption("digits"))

## Arguments

$x \quad$ Clifford object
drop Boolean with default TRUE meaning to coerce the output to numeric with drop()
digits number of digits to retain

## Details

Given a clifford object, coefficients close to zero are 'zapped', i.e., replaced by ' 0 ' in much the same way as base::zapsmall().
The function should be called zapsmall(), and dispatch to the appropriate base function, but I could not figure out how to do this with S3 (the docs were singularly unhelpful) and gave up.
Note, this function actually changes the numeric value, it is not just a print method.

## Author(s)

Robin K. S. Hankin

## Examples

```
a <- clifford(sapply(1:10,seq_len),90^-(1:10))
zap(a)
options(digits=3)
zap(a)
a-zap(a) # nonzero
```

```
B <- rblade(g=3)
\(m B<-B * \operatorname{rev}(B)\)
zap(mB)
drop(mB)
```

zero The zero Clifford object

## Description

Dealing with the zero Clifford object presents particular challenges. Some of the methods need special dispensation for the zero object.

## Usage

```
is.zero(C)
```

## Arguments

C

## Clifford object

## Details

To create the zero object $a b$ initio, use
clifford(list(), numeric(0))
although note that scalar(0) will work too.

## Author(s)

Robin K. S. Hankin

## See Also

scalar

## Examples

is.zero(rcliff())
